# STARCH.

By DR. H. W. WILEY.

A comparative summary of the starch manufacture of the United States from 1850 to 1900, inclusive, with percentages of increase for each decade, is given in Table 1.

TABLE 1.—COMPARATIVE SUMMARY, 1850 TO 1900, WITH PER CENT OF INCREASE FOR EACH DECADE.

	DATE OF CENSUS.						PER CENT OF INCREASE.				
	1900	1890	1880	1870	1860	1850	1890 to 1900	1880 to 1890	1870 to 1880	1860 to 1870	1850 to 1860
Number of establishments	124	80	189	195	167	146	55.0	142.4	128.7	16.8	14.4
Capital	\$11,671,567	\$4,929,155	\$5,328,256	\$2,741,675	\$2,051,710	\$692,675	136.8	17.5	94.3	33.6	195.2
Salaries	406	218	(3)	(3)	(3)	(3)	86.2	.....	.....	.....	.....
Salaries	\$451,834	\$229,909	(3)	(3)	(3)	(3)	96.3	.....	.....	.....	.....
Wage-earners, average number	2,855	2,908	3,119	2,072	1,078	694	18.5	16.9	50.5	93.1	54.6
Total wages	\$1,099,696	\$959,108	\$919,197	\$900,719	\$298,526	\$193,224	14.7	4.3	2.1	201.7	54.5
Men, 16 years and over	2,088	2,307	2,710	1,712	1,063	636	19.5	114.9	53.3	61.1	55.0
Wages	\$986,852	\$840,730	(3)	(3)	(3)	(3)	17.4	.....	.....	.....	.....
Women, 16 years and over	555	484	301	317	10	8	10.5	60.8	15.0	5,070.0	25.0
Wages	\$107,720	\$105,362	(3)	(3)	(3)	(3)	2.2	.....	.....	.....	.....
Children, under 16 years	32	112	108	43	.....	.....	171.4	8.7	151.2	.....	.....
Wages	\$5,124	\$12,969	(3)	(3)	(3)	(3)	160.5	.....	.....	.....	.....
Miscellaneous expenses	\$700,277	\$1,108,185	(4)	(4)	(4)	(4)	156.8	.....	.....	.....	.....
Cost of materials used	\$5,806,422	\$5,153,677	\$4,911,050	\$3,884,909	\$1,880,000	\$799,459	12.7	4.9	26.4	151.5	72.6
Value of products	\$9,232,984	\$8,934,517	\$7,477,742	\$5,994,422	\$2,823,258	\$1,261,468	3.3	19.5	24.7	112.3	128.2

<sup>1</sup> Decrease.

<sup>2</sup> Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 7.)

<sup>3</sup> Not reported separately.

<sup>4</sup> Not reported.

The data of this table show that the amount of capital increased in fifty years from \$692,675, invested in 146 establishments, to \$11,671,567 invested in 124 establishments, an increase of \$10,978,892; wages from \$193,224 to \$1,099,696, an increase of \$906,472. The smaller increase in wages is due in part to the fact that the technical operations in starch making have been

greatly improved, requiring a smaller proportion of labor. The total cost of the materials used increased from \$799,459 to \$5,806,422, or \$5,006,963; the value of products from \$1,261,468 to \$9,232,984, or \$7,971,516.

Table 2 is a comparative summary, by states, for 1890 and 1900.

TABLE 2.—COMPARATIVE SUMMARY, BY STATES: 1890 AND 1900.

<sup>1</sup> Reported in "all other states" in 1900.<sup>2</sup> Reported in "all other states" in 1890.<sup>3</sup> Includes establishments distributed as follows in 1900: California, 2; Florida, 2; Maryland, 1; Nebraska, 2; New Jersey, 1; North Dakota, 1; Pennsylvania, 1. In 1890: Illinois, 1; Kansas, 1; Nebraska, 1; New Hampshire, 1; Pennsylvania, 1; Rhode Island, 1; Vermont, 2; Wisconsin, 2. Kansas, Rhode Island, and Vermont not reported in 1900.<sup>4</sup> Not reported in 1890.<sup>5</sup> Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 7.)

While the value of products as a whole increased 3.3 per cent during the decade, 1890 to 1900, a decrease is shown for a number of states. This is particularly noticeable in New York, where it was 35.5 per cent; in Indiana, 37.4 per cent; and in Ohio, 15.2 per cent. This may be in part attributed to changes in the location of the manufacture, owing to an industrial combination.

New York was first in rank, Indiana second, and Ohio third; the same positions they held in 1890.

Table 3 shows the distribution of establishments, 1890 and 1900, by states geographically arranged, with increase for the decade.

TABLE 3.—NUMBER OF ESTABLISHMENTS, 1890 AND 1900, WITH INCREASE DURING THE DECADE, BY STATES, ARRANGED GEOGRAPHICALLY.

Pacific states.....	2	.....	2
California.....	2	.....	2

<sup>1</sup> Decrease.

The greatest increase in number of establishments, 28, was in the New England states, but they were mainly small factories. The Central states show the next greatest increase, 13, the Western states having an increase of 1 and the Middle states of 1.

Table 4 shows the capital invested in 1890 and 1900, with percentages of the total for each decade.

TABLE 4.—CAPITAL: 1890 AND 1900.

	1900		1890		Per cent of increase.
	Amount.	Per cent of total.	Amount.	Per cent of total.	
Total.....	\$11,671,567	100.0	\$4,929,155	100.0	186.8
Land.....	2,464,141	21.1	324,011	6.6	460.5
Buildings.....	3,287,110	28.2	1,377,608	27.9	188.6
Machinery, tools, and implements.....	3,119,703	26.7	1,046,036	21.2	198.2
Cash and sundries.....	2,800,613	24.0	2,181,500	44.3	28.4

The data in this table show that the percentage of capital invested in land has increased from 6.6 to 21 during the ten years. This discloses the urban location of many of the plants. Capital invested in buildings increased 188.6 per cent, and in machinery, tools, and implements 198.2 per cent.

Of the miscellaneous expenses 1.2 per cent was for rent of works, 5.7 per cent for taxes, not including internal revenue, 92.7 per cent for rent of offices, insurance, interest, advertising, and other sundries, and four-tenths of 1 per cent for contract work.

The quantity of materials used in a geographical subdivision is governed by the extent of the manufacture there located. The Central states produced the most starch in 1900, and therefore used the most material, or 47 per cent of the total value. The Middle states used 31.9 per cent, and the New England states 15.8 per cent. The remainder, 5.3 per cent, was divided between the Western states and "all other states." The cost of indian corn was 46.9 per cent of the total materials, and of potatoes 12.1 per cent. These are the chief materials of the manufacture.

Of the value of products 13 per cent comprises by-products, including cattle food. (See Table 7.) Of the starch made 76.3 per cent was corn starch, and 14 per cent potato starch. The 9.7 per cent remaining was divided between wheat and root starch.

The total quantity of starch manufactured was 297,803,139 pounds. Of this total, 247,051,744 pounds were made from indian corn, and 50,751,395 pounds from all other materials. The average value per pound of indian corn starch was 2.5 cents, and the average value of all other starches was 3.8 cents per pound.

The reason of the increased value of starches from other sources than indian corn is due to the peculiar properties which these bodies have for special purposes. This is illustrated by the fact that for use in the textile industries potato starch is preferred to that made from indian corn, and a higher price is paid therefor by the manufacturers. Starches from which

tapioca and similar bodies are made bring a higher price on account of the particular uses to which they are put. For laundry purposes, for the manufacture of glucose, and largely for edible purposes the indian corn starch is cheaper and is in almost universal use in the United States.

Excluding glucose, which can not be regarded as a by-product in the manufacture of starch, cattle foods are the principal by-products. The refuse coming from the manufacture of starch from potatoes is of less value than that coming from indian corn, and hence in

Maine, which is the principal state for the manufacture of potato starch, there is no by-product mentioned which is used for cattle foods. Observations of the starch factories in Maine bear out this statement. In a large number of them it was found that the pulp was not used for any purpose whatever. The same statement may be made regarding Minnesota, where no cattle food was reported as a by-product.

Table 5 is a summary for starch made from materials other than potatoes, 1900, arranged by states according to rank.

TABLE 5.—STARCH, OTHER THAN POTATO: SUMMARY, BY STATES, 1900.

### HISTORICAL AND DESCRIPTIVE.

Starch is one of the principal components of all cereal grains, and of certain root crops, such as the potato, the sweet potato, the cassava, and others. The most important uses of starch are, first, in the laundry; second, for the manufacture of glucose; third, for edible purposes; and fourth, for use in the textile industries. The principal commercial sources of starch are the cereals and potatoes. In the United States indian corn is the principal cereal employed in making starch for commercial purposes. The only other cereal which is used to any extent is wheat, and the use of this cereal

is extremely limited. A large number of establishments in the United States also produce starch from potatoes, but in a very small way. Practically five-sixths of the commercial starch of the United States is derived from indian corn. In Europe the principal source of starch is the potato, and this tuber is used very extensively both on the Continent and in England for this purpose. In tropical countries considerable quantities of starch are made from the different varieties of the cassava, and this industry has lately been introduced into the United States, since cassava grows

well in Florida and some other southern parts of the United States. The starch made from the varieties of the cassava is used either as indicated above or for the manufacture of the food product known as tapioca.

The methods of manufacturing starch used either for pure starch, on the one hand, or the manufacture of glucose on the other, is as follows: Grades of indian corn numbers 2, 3, and 4, and grains of no grades are used, but chiefly number 2. The corn is bought shelled in the open market. Cobs and leaves are removed by means of an inclined mechanically shaken sieve through which the grain passes; dirt and fine dust are removed by fans; and nails and other iron scraps are removed by magnets. Large tanks made of wood, iron, or copper, with a capacity of about 1,000 bushels, are used for steeping or softening the corn. Water charged with three-tenths of 1 per cent of  $\text{SO}_2$  (sulphurous acid) and heated to  $125^\circ \text{F}$ . is used for the softening of the grain; the water is circulated from the bottom to the top by means of a steam injector, and from twenty-four to thirty-six hours are required to complete the steeping. The soft, warm grains are ground or "cracked" with ordinary  $4\frac{1}{2}$ -foot French burr mills; the grinding being only carried far enough to loosen the germ, and not break it. The "cracked" mass is threshed three times in order to complete the loosening of the germ. The thresher is a box containing 2 circular shafts, fitted with blunt steel arms, making from 1,500 to 2,000 revolutions per minute. The threshed mass is passed between rubber-faced rolls, and the excess of starch liquor is removed from the germ, etc. The wringer is an ordinary five-roller laundry wringer carrying an endless steel gauge belt between the rolls. Technically they are known as "slop machines."

The semidried mass is fed into the "germ separators," where, in consequence of the difference in specific gravity between the germ and shells, the germ floats and the shells sink in a starch solution of  $8.5^\circ \text{Baumé}$ . The germ and some starch liquor overflow at one end and at the top of the separator, and the shells and a little more starch liquor are removed from the bottom by a motor pump. To facilitate the removal of the germ, paddles or sweeps drag the germs to the point of overflow and a screw-conveyor form of agitator in the bottom of the separator does the same for the shells. The separator is much like a masse-cuite mixer. It is filled and kept filled with  $8.5^\circ \text{Baumé}$  starch liquor.

From the separators the germ and the starch liquor are fed upon a great many copper sieves or "shakers," where the starch liquor is removed from the germs and the germ is freed from adhering starch by washing with water. The shakers are set at a slight angle and are given about 400 lateral throws of  $1\frac{1}{2}$  inches per minute. The shaker bottom is covered with a perforated sheet of copper. The washing water comes from small V-shaped troughs running crosswise of the shakers and having their sides perforated.

The germ is put into large sacks or cloths of coarse mesh and subjected to a pressure from a hydraulic press. From this press the germ enters a revolving steam-heated dryer, much like a sugar granulator, and all but 3 per cent of the moisture is removed. A suction fan removes any dust or light particles. The dried germ is run into aspirators, where the shell and points of the germ are removed by fans and screens, and after cooling it is fed to a five-roller shell mill, where it is ground to a fine meal. The mills are of the regular linseed-mill pattern, with one roll set over the other. After grinding, the germ or meal is fed into a double-bottom steam heater or cooker, and from this into another, and at the same time a small jet of steam plays on it as it is moved about by the agitators, in order to supply the required moisture. The meal is heated until it is just bearable to the hand.

The heated meal is fed from the bottom of the cooker into a form; this form in turn drops the meal on a cotton cloth, and the attendant folds over the ends of the cloth, and by means of a piston driven by steam, forms and compresses the cake. The formed cake is slipped between the plates of a regular oil press holding 16 cakes. A hydraulic pressure of 4,000 pounds to the square inch removes 90 per cent of the oil. The oil is filter-pressed through cloth or paper and allowed to settle in large iron tanks for several days. After this it is barreled and is sold in this form of package. The oil cake containing 10 per cent of oil is sold as a cattle food, principally in Europe.

The shells and other unground parts that are removed from the bottom of the germ separator are called the "first grind." From the separators this is fed upon rapidly oscillating silk sieves or shakers. Here the mass is drained, the starch liquor passing through the silk and going to the starch supply tank. The drained first grind is fed into a second net of burr mills, when the starch adhering to the shells is removed as far as practicable.

The feed or second grind is fed upon silk sieves or shakers. The first half of the shake simply drains the starch from the second grind without any washing. These drainings are also sent to the starch-supply tank and are washed five times in passing over the second or last half of the shakers in order to remove all adhering starch. The feed passes through a set of wringers for the final removal of any free starch. It is then mixed with the solids from the "steep water," and the gluten is pumped into large presses, where 45 per cent of the adhering moisture is removed. These presses are very large, carrying 100 plates, and are operated by hydraulic pressure.

The feed after being broken by threshers is carried into large steam dryers, where the moisture is reduced to 20 per cent. After again passing through threshers it is conveyed into the finishing dryers, where all but about 10 per cent of moisture is removed. It is then ground

to a fine meal by food attrition mills, which have two flat disks revolving in opposite directions at a speed of 2,000 revolutions per minute. The disks have little square pockets, one-fourth by 1 inch and one-fourth inch deep, giving an enormous cutting surface. The feed is sold as gluten, buffalo-maize, and golden feed, and is one of the well-known concentrated cattle feeds in the market.

The washings of the second grind on the second shakers that are very dilute are run into cone settlers, where the excess of water is removed and the concentrated starch liquor is sent to the starch-supply tank. These cone settlers are circular iron tanks, with cone bottoms, and are about 12 feet deep. The starch enters a 10-inch pipe, extending from the top to within 36 inches of the bottom. The point of the cone has a one-half-inch outlet for removing the starch. The water overflows at the top of the tank. By this arrangement the settling and drawing off of the water and starch are continuous. The accumulated starch liquors are collected in the supply tank from all parts of the house, after being run upon a set of silk shakers carrying a very fine mesh silk, known as No. 20. These shakers remove the finer particles of feed, etc.

From the shakers the starch is fed in small streams to the starch tables, where the starch settles and the gluten runs off at the end of the table. The tables are long gutters, 20 inches wide, 9 inches deep, and 100 feet long, with a fall of about 4 inches in that length. When the tables are filled sufficiently the starch is scraped with rubber-edged scrapers and is shoveled upon carriers. These carriers empty into large 12-foot tubs or "breakers," where the starch is mixed with enough water to make a solution weighing either 24° Baume', or 6° Baumé. The 6° starch is again passed over No. 20 shakers and is then run on another set of tables to remove any adhering gluten or other impurities carried off by the water. After scraping, or rubbing and draining, the starch is removed from the tables by carriers.

From the carriers the starch is fed into breakers or threshers, and, after being broken into pieces the size of a hen's egg, it is loaded into shallow canvas-bottom trays. These trays are put on a wagon and the wagon run into kilns. These wagons are run on tracks, and are fitted with racks to hold 14 trays equaling 1 bag of starch, or 300 pounds. The starch remains in the kiln twelve hours, and is gradually moved from the air outlet end of the kiln to the hot air inlet end. These kilns are narrow tunnels holding 16 cars; a temperature of 140° is maintained, and the heated air enters at one end and is drawn out at the other. The starch, containing about 10 per cent of moisture, is powdered either by rolls or beaters and then passed through silk-bolting machines. Pearl starch is that which is not milled after drying but is sold in small masses of a pseudo-crystalline structure. The starch before sending to market is either sacked or barreled.

*Twenty-four Degree or Glucose Starch.*—The 24° Baumé starch is pumped into the refinery breakers, where it is mixed with one-fourth of 1 per cent concentrated muriatic acid, and is pumped into the converters. The converters are horizontal copper cylinders, 6 by 20 feet, holding 2,000 gallons of starch liquor. A perforated steam coil is in the bottom of the converter and a similar perforated pipe in the top is the inlet for the starch. Before pumping in the starch the steam coil is covered with an acidified water which is brought to a boil. The starch is pumped in, just fast enough not to cool the water below the boiling point, under a pressure of 20 pounds to the square inch. When all of the starch is in the converter the pressure is raised to 35 pounds, and is held at this for twelve minutes, or until the desired sodine test for glucose containing 55 per cent of dextrose is obtained. For acme sugar containing 85 per cent of dextrose the starch is diluted to 14° Baumé and held at a pressure of 45 pounds for forty-five minutes. For brewing sugar containing 93 per cent of dextrose the starch is diluted to 18° Baumé and held at a pressure of 40 pounds for twenty minutes.

The conversions are forced into blow-up tubs, which are large open tubs for relieving the pressure on the converters. From these tubs it flows into neutralizers, where all but 0.015 per cent of the acidity is neutralized with soda ash. From the neutralizers the liquor enters settling tanks for the removal of the coagulated gluten and fibrous matter or it is pumped into regular sugar presses at once.

The liquors from the presses are passed over or through boneblack until all of the color is removed. These filters are horizontal cylinders, 20 by 6 feet, filled with animal black. The liquor enters at the top and is drawn out at the bottom. The filters will usually run from fifteen to eighteen hours. From the filters the liquor is drawn into vacuum pans and is evaporated under 27° to 30° Baumé. From the vacuum pans the liquor is passed through another set of black filters to remove the color that has been generated in the evaporation. These filters are like the first filters, but contain freshly burned black and are only run four hours. After this liquor has exhausted the black it is used for light liquors. From the filters the liquor is drawn into the finishing pan and evaporated to the required density. For glucose either 41°, 42°, 43°, 44°, or 45° Baumé are required. For 70 sugar 41° and for acme or 80 sugar 45° Baumé are required. All weighings are made at 100° F. The pans are regular sugar vacuum pans holding about 63 pounds of glucose.

The glucose from the pans is run into cone-bottom iron tanks fitted with cooling pipes. After cooling the glucose to 100° F., a little bisulphite of soda is added to prevent fermentation, and a little aniline violet to neutralize any tinge of yellow. The glucose is drawn into barrels, and sold at 1 to 1½ cents per pound.

The sugar from the vacuum pans in the case of 70 sugar is drawn into a cooler, and to it are added several buckets of previously crystallized sugar. In this way crystallization is induced. The sugar is then drawn into barrels or pans, where it crystallizes and becomes solid in eighteen hours at normal temperature. The acme is handled in the same manner, but is all crystallized in pans in a room heated to 115° F. Thirty-six hours are required for the acme crystallization, and then thirty-six hours more in a cold room for curing. The panned sugar is chopped and sold in bags. Anhydrous sugar is handled much in the same way as the other, only that the starch is diluted to 1½° Baumé and the plextrorse is carried to the maximum. The crystallization is done in cones or forms in a hot room. The cones are made to fit a centrifugal, in which the sugar is freed from adhering sirup. The sugar is shaved and air-dried for several days, and is sold in barrels at 4½ to 5½ cents per pound.

The so-called gluten drawn from the tabled starch is first settled for five hours in wooden tubs, and then the concentrated mass is further concentrated in cone settlers. It is then mixed with the feed and sent to the presses. The steep water from the steeps is first acidified with sulphuric acid to remove the sulphurous acid. It is evaporated to 10° Baumé and neutralized with milk of lime. The precipitate formed is removed by filter presses. The liquor is then evaporated to 30° Baumé and again mixed with the lime precipitate. It is then mixed with the pressed feed.

In the above description no attempt has been made to go into the details of the manufacture, but simply to give the general principles which are followed. In different factories different details of manufacture would be found, but in general the large factories making indian corn starch follow essentially the methods given above.

*Starch from Potatoes.*—The principles underlying the manufacture of starch from the potato are very simple in their mechanical application. The problem is very much less complicated than in the case of indian corn, since there are no by-products which are worth saving

except the pulp, hence no apparatus is necessary for the removal of the outer hull or of the germ. Potatoes of all sizes are used, but chiefly what is known as the culls or immature tubers, or those which are injured in digging and are unsuitable for sending to the market for food purposes. The state of the markets is usually such that there is more profit in selling well-formed and mature potatoes of good size for direct consumption than there is in sending them to the starch factories.

Usually when the price of good, marketable potatoes approaches \$1 per barrel, farmers find it more profitable to sell for direct consumption. In a personal inspection of the potato-starch industry in Aroostook county, Maine, made by the author in 1899, potatoes fit for consumption on the table were selling for a dollar a bushel, while the starch manufacturers were paying only from 30 cents to 60 cents per bushel for potatoes used in the manufacture of starch. It is evident that the quantity of starch in such potatoes is very much inferior to that in the merchantable potatoes sold at a higher price. The yield of commercial starch varies from 10 to 16 per cent of the weight of the potatoes used, according to the character and grade of the raw material employed. In Germany potatoes particularly rich in starch are grown especially for starch making. It is not a matter of wonder, therefore, that the yield of starch from the American factories is lower than from the German factories for the same weight of potatoes.

The process of manufacture of potato starch is very simple; in fact the housewife can make a very good potato starch by rasping the potato on a piece of sheet iron punctured with numerous holes by an ordinary awl, throwing the pulp upon a fine cloth and washing the starch through with a stream of water.

A complete study of the potato as a source of starch making, and the details of manufacture, are discussed in Bulletin No. 58 of the United States Department of Agriculture, Bureau of Chemistry.

Table 7 is a detailed summary for the entire starch manufacture, 1900, by states.

# COTTONSEED PRODUCTS.

By DANIEL C. ROPER, *Expert Special Agent.*

Reports have been received from 357 establishments engaged in the manufacture of cottonseed products during the census year ending May 31, 1900. These establishments are located in 15 different states and territories, but it is impossible to publish separate totals for 4 of these states without disclosing the operations of individual establishments. The statistics for these 4 states are therefore grouped under the head of "all

other states" in the tables of this report, and include establishments distributed as follows: Florida, 1; Kansas, 1; Missouri, 2; and Illinois, 1.

Table 1 shows by states and territories and for the United States the number of establishments, the quantity and cost of cottonseed crushed for oil extraction, and the quantity and value of each of the products, together with the total value of all products.

TABLE 1.—NUMBER OF ESTABLISHMENTS, QUANTITY, COST, AND AVERAGE COST PER TON OF COTTONSEED CRUSHED; AND QUANTITY, VALUE, AND AVERAGE VALUE PER UNIT OF PRODUCTS MANUFACTURED: 1900.

STATES AND TERRITORIES.	Number of establishments.	COTTONSEED.			PRODUCTS.

<sup>1</sup> Includes establishments distributed as follows: Florida, 1; Kansas, 1; Missouri, 2; Illinois, 1.

The cost of the cottonseed crushed for oil extraction was \$28,632,616 and the values of the products were as follows: Oil, \$21,390,674; cake and meal, \$16,030,576; hulls, \$3,189,354; linters, \$1,801,231—a total of \$42,411,835. The value of the seed was increased 48.1 per cent by the manufacture.

The refining of oil and the manufacture of fertilizers were conducted in connection with oil extraction by a number of the establishments reported in Table 1, but this report does not cover any operation subsequent to the extraction of oil. Statistics of cottonseed oil refining are not included, both because such operations do not come within the proper scope of this report, and because it is impracticable to present statistics of the quantity of oil refined without danger of duplication, owing to the different stages of refinement in which the oil is purchased by different mills. This report, moreover, does not show the capital, wages, and miscellaneous expenses of the establishments, for the reason that it has been impracticable to differentiate the capital, labor, and expenses covering the several industries included in the operations of these establishments so as to present such statistics for oil extraction only. In comparing the statistics of this report with the general statistics of manufacturing industries, it should be remembered that the classification "oil, cottonseed, and cake," in the general statistics, includes, in addition to the industry covered by this report, the refining of cottonseed oil and some manufacturing of fertilizers. The value of products, as given in the general statistics, includes also the value of a considerable quantity of fertilizers manufactured at the oil mills by combining cottonseed meal with phosphate rock. The statistics of mills which crush cottonseed for use as a fertilizer without extracting oil are not included in this report, but are included in the general tables of manufactures under the classification "fertilizers."

Among the economic developments which have characterized the industrial progress of the United States during the past quarter of a century, none has attracted more attention and brought about more desirable results than the manufacture of cottonseed products. In the Mississippi Valley and other sections of the country where fertilizers were not required for replenishing the soil, the disposal of cottonseed gave the ginner and the community great concern prior to 1860. The seed was usually hauled to a remote place to rot, or dumped into some convenient stream of running water. With the growth of population and increase in cotton culture this careless method of disposal often became a great

nuisance. In this connection the following extract from one of the laws of Mississippi is interesting history:

ARTICLE 18. Every owner or proprietor of any cotton gin erected within half a mile of any city, town, or village is hereby required to remove or destroy all cottonseed which may fall from such gin, so that the same shall not prejudice the health of the inhabitants of such city, town, or village; and every person being an owner or proprietor of a cotton gin situate as aforesaid, who shall neglect or refuse to remove or destroy the cottonseed in and about such gin, having received five days' notice, shall forfeit and pay the sum of \$20 for every day he or she shall neglect or refuse to remove or destroy the cottonseed as aforesaid, to be recovered by warrant in the name of the state before any justice of the peace of the proper county for the use and benefit of said county.

ARTICLE 19. No person who shall be the owner or proprietor of any cotton gin shall be authorized to throw or permit to be thrown the cottonseed from such gin into any river, creek, or other stream of water which may be used by the inhabitants for drinking or fishing therein; and any person offending herein shall forfeit and pay for every such offense the sum of \$200, to be recovered in any court of competent jurisdiction, by action of debt or information in the name of any person who will sue for the same, one moiety thereof to such person and the other moiety to the county in which the offense is committed.<sup>1</sup>

The low commercial rating of cottonseed so vividly indicated in this law was current in these localities until the introduction of the intensive system of cotton farming, which is practically coeval with the introduction of the cottonseed-oil mill; although, in localities where the soil required replenishing, a few thrifty farmers early began the use of the seed as a fertilizer. In its early use as a fertilizer the seed was made into a compost, or exposed to the weather for a sufficient time to destroy the germ life. While in many localities these methods are still in vogue, yet the more general plan is to destroy the germ life by crushing the seed. This manner of using cottonseed was found to involve great waste, when it was discovered that through the manipulations of the oil mills all of the value of the seed as a fertilizer was retained, and at the same time it was, through its by-products, made to contribute marvelously to the general economy of wealth. The result is that from a product that was deemed a nuisance in 1857 there was produced in 1900 a value of \$42,411,835, and only 53.1 per cent of the available raw material was utilized.

Table 2 shows by states and territories and for the United States the number of establishments, the average consumption of cottonseed per establishment, the average quantity and value of the several products manufactured from one ton of seed, and the per cent that each is of the total weight and value.

<sup>1</sup>Revised Code of Mississippi: 1857, page 207.

<sup>1</sup> Includes establishments distributed as follows: Florida, 1; Kansas, 1; Missouri, 2; Illinois, 1.  
<sup>2</sup> Estimated on the basis of 7.5 pounds per gallon.

At the census of 1870 but 26 cottonseed-oil mills were reported. The number increased to 45 in 1880, 119 in 1890, and 357 in 1900; an increase of 73.1 per cent between 1870 and 1880; 164.4 per cent between 1880 and 1890; and 200 per cent between 1890 and 1900. But it should be noted that the censuses prior to 1900 included all establishments engaged in refining cottonseed oil, while, as previously explained, this report includes only such establishments as are engaged in extracting the oil; accordingly, the figures given above are probably not quite correct as regards the increase between 1890 and 1900.

The general average consumption of seed per establishment for the season covered by the census year was 6,945 tons.

Table 2 shows the average quantity of products per ton of seed for the United States in 1900, as follows: Crude oil, 37.6 gallons (equivalent to 282 pounds); cake and meal, 713 pounds; hulls, 943 pounds; linters, 23 pounds; and waste, 39 pounds.

Table 3 is a statement of the number of gallons of cottonseed oil exported from 1870 to 1901, inclusive, together with the total value and the average value per gallon.

<sup>1</sup> Commerce and Navigation of the United States.<sup>2</sup> The value of cottonseed oil, at the time of exportation, in the ports of the United States whence exported.<sup>3</sup> Quantity not stated.

The first cottonseed-oil mill in the United States was erected at Natchez, Miss., in 1834, but the industry did not acquire commercial importance until after the Civil War. In fact, the history of the industry prior to 1870 records more of failure than success. The quantity of cottonseed crushed and the resulting products were not reported prior to the present census. It is therefore impossible to trace the growth of this industry statistically, except in so far as it is indicated by the exports which are presented in Table 3. In the earlier years of its manufacture, cottonseed oil was almost entirely exported to foreign countries, and export figures for those years, therefore, represent very nearly the production of the country. The export of cottonseed oil in 1872 was 547,165 gallons, and it is estimated that approximately 3 per cent of the cottonseed produced in that year was required for the production of this quantity of oil. The export in 1880 was 6,997,796 gallons, and represented a consumption of 20 per cent of the seed produced in that year. It would not be safe to estimate on this basis for 1890, as by that time the home consumption of cottonseed oil had become an important factor.

The export of cottonseed oil in 1900 was 46,902,890 gallons, which constituted 50.2 per cent of the total production for that year.

Table 3 further shows that in 1872 and 1899 cottonseed oil reached its maximum and minimum prices, commanding in the former year 53.6 cents, and in the latter 23.9 cents per gallon in the ports from which it was exported. The low price in 1879 was due to the large quantities of oil obtained from the seed crops of 1878 and 1879. The increase in the production from 281,054 gallons in 1876 to 5,352,530 gallons in 1879 was much in excess of the supply required for the limited field in which it was then utilized. About this time, however, it was discovered that cottonseed oil could be advantageously combined with beef fat to make a substitute for lard. Then followed the further discoveries that this oil could be utilized in packing American sardines and, in combination with other substances, in making artificial butter. This increased the demand and gave a permanent stimulus to the industry.

Table 4 is a statement of the quantity and value of cottonseed oil exported to each country.

Table 4 shows that Europe received 39,061,992 gallons, or 83.3 per cent of the quantity of cottonseed oil exported in 1900. France received 13,595,564 gallons, which was 34.8 per cent of the European consignment and 29 per cent of the total exported. The Netherlands received 9,411,170 gallons, which was 24.1 per cent of the European consignment and 20.1 per cent of the total quantity exported.

The better grades of oil are exported to the Netherlands, where they are made into artificial butter, while the inferior grades are sent to France for use in making soap.

Table 5 is a summary, by states and for the United States, of the value of the lint cotton produced during the census year; the quantity and actual value of the seed, and the value it would have if crushed for oil; the quantity and cost of seed actually crushed, and the value of its products; the actual value of the cotton crop, and the value it would have if all the seed were crushed; the percentages that the value of the seed and the potential value of its products are of the value of the crop, and that the seed crushed is of the entire quantity produced; and the percentage of the increase in value by manufacture.

<sup>1</sup> Does not include \$337,464.04, the value of the cotton product of Virginia and Kentucky, there being no oil mills reported from those states.  
<sup>2</sup> Includes the statistics reported by establishments distributed as follows: Florida, 1; Kansas, 1; Missouri, 2; Illinois, 1.

It is not to be assumed that the statistics of cotton and seed production, and the percentages derived from them, presented in the foregoing table under "all other states," apply to Illinois, there being no cotton grown in that state.

In ascertaining the value of the cotton crop of 1899, the net quantity of cotton produced, as reported by the ginners, has been multiplied by the average price per pound, or 7.2 cents for upland and 14.4 cents for sea-island cotton, as given in "The Cotton Crop of 1899-1900," issued by the United States Department of Agriculture.

The quantity of seed produced has been ascertained as previously explained, and the value by multiplying the total quantity produced by the average price paid for that portion of the seed which was used by the cottonseed-oil mills. The values of the lint and seed constitute the total value of the cotton crop.

From Table 5 it will be seen that more seed was crushed in Tennessee than was produced in that state. This was due to the fact that several large cottonseed-oil mills located in Memphis used seed produced in Mississippi and Arkansas. Of the seed produced in the state, in each case, Alabama crushed 33.4 per cent; Arkansas, 56.3; Georgia, 46.2; Indian Territory, 38.3; Louisiana, 75.0; Mississippi, 66.7; North Carolina, 51.3; Oklahoma, 76.1; South Carolina, 39.2; and Texas, 55.4. Of the total amount of seed produced in the United States, 55.4 per cent was used by the oil mills.

Table 5 shows also that the value of the seed was increased 48.1 per cent by the manufacture. The value of the entire seed crop, as shown by the table, was \$51,904,816, or 13.8 per cent of the total value of the cotton crop, including the value of the seed, while the value of the products from the manufacture of all the seed produced would have been \$76,988,152, or 20.5 per cent of the total value of the cotton crop. The value of the total seed crop to the farmers is represented by the former figure. The products obtained from the manufacture of 53.1 per cent of the seed crop were valued by the mills at \$42,411,835. The economic value produced by crushing this seed was \$13,779,219, and had the entire production of seed been crushed, \$25,083,336 would have been added to the general economy of wealth. These values would be materially increased by including the value of the meal after it has been converted into fertilizers, and the value of oil after it has been carried through its various channels of refinement.

Table 6 is a statement of the quantity and value of the several crude products obtainable from 1 ton of cottonseed.

TABLE 6.—CRUDE PRODUCTS PER TON OF COTTONSEED.

PRODUCTS.	Quantity.		Value.	
	Pounds. 2,000	Per cent. 100.0	Dollars. 17.09	Per cent. 100.0
Total.....				
Oil.....	282	14.1	8.61	50.4
Cake and meal.....	713	35.7	6.48	37.9
Hulls.....	943	47.1	1.29	7.5
Linters.....	23	1.1	0.71	4.2
Waste.....	39	2.0		

Considering the average value of a ton of cottonseed as \$11.55, the increase in value by its manufacture, as revealed by the above table, is \$5.54.

WASTE.—Upon reaching the oil mill the seed is screened for the purpose of removing sand, bolls, leaves, and sticks. The quantity of these foreign particles varies in different localities, according to the care used in picking and the natural condition of the seed, which is itself variable with soils and seasons. Seed produced on light soil often carries considerable sand. The average waste in screening, for the United States, as shown in Table 1, was 39 pounds per ton, leaving for the further processes 1,961 pounds for each 2,000 pounds of seed entering the mill.

LINTERS.—More or less short lint, called "linters," adheres to the seed as it comes from the gin, according to the character of the machinery used and the variety of seed. Sea-island cottonseed is entirely freed from lint by the first ginning, and is therefore not reginned at the oil mill before being crushed for oil extraction. Upland cottonseed varies in the quantity of lint which remains after the first ginning, some carrying considerable lint, while other seed approaches very closely to the condition of the sea-island variety. Table 2 shows that the quantity of lint secured by the oil mills from the necessary reginning of the seed varied from 19 to 26 pounds per ton, and that the average for the United States was 23 pounds per ton. This short lint was sold at an average price of 3.1 cents per pound. The total quantity obtained was 57,272,053 pounds, valued at \$1,801,231.

HULLS.—From the delinting machinery the seed passes to the grinders, where it is cut into pieces, then to a revolving screen so constructed that the meats fall through its meshes and the hulls roll out as tailings, while supplementary shakers make the separation of the meats and hulls complete.

In the beginning of the industry, hulls were often used as fuel in the engines, the ashes being utilized as a fertilizer. This custom, however, has largely been abandoned since the discovery of better uses for the hulls. These hulls are beginning to contribute largely to the wealth of the country. Paper stock made from them has already attracted attention, and one or two plants have recently been erected for this manufacture.

Cattle feeding is, however, by far the most useful purpose to which these hulls have yet been applied, and this use of the product is one which must greatly increase. A mixture of ground hulls and cottonseed meal makes one of the best feeds known to the stock-raising and dairy industries. The proportions employed are about five parts hulls to one of meal in weight. "Two and a half million tons of hulls will fatten for market an equal number of heavy beef cattle, or maintain that number of dairy cattle."<sup>1</sup> The possession of this seed, with all the essential elements of animal food which it contains, may enable the South to

<sup>1</sup> Cotton and Cotton Oil, by D. A. Tompkins

compete with the Northwest in producing the meat supply of the country. The quantity of hulls secured from the seed crushed in 1900 was 1,169,286 tons.

**MEAL AND CAKE.**—Stripped of lint and hulls, the cottonseed meats or kernels are heated and subjected to hydraulic pressure to extract the oil. The compact residue, known as cake, was formerly used in this condition for cattle feed, and formed a large percentage of the cottonseed products exported. The plan of mixing hulls and meal as a feed and the use of meal as a fertilizer has brought about the present almost universal plan of grinding the cake into meal both for domestic uses and foreign export. Indeed, the prevailing use of this meal is that of a fertilizer. It either goes directly into this channel in its original state or becomes an important element in the manufacture of commercial fertilizers. The demand for meal as a cattle feed is rapidly increasing in states west of the Mississippi River.

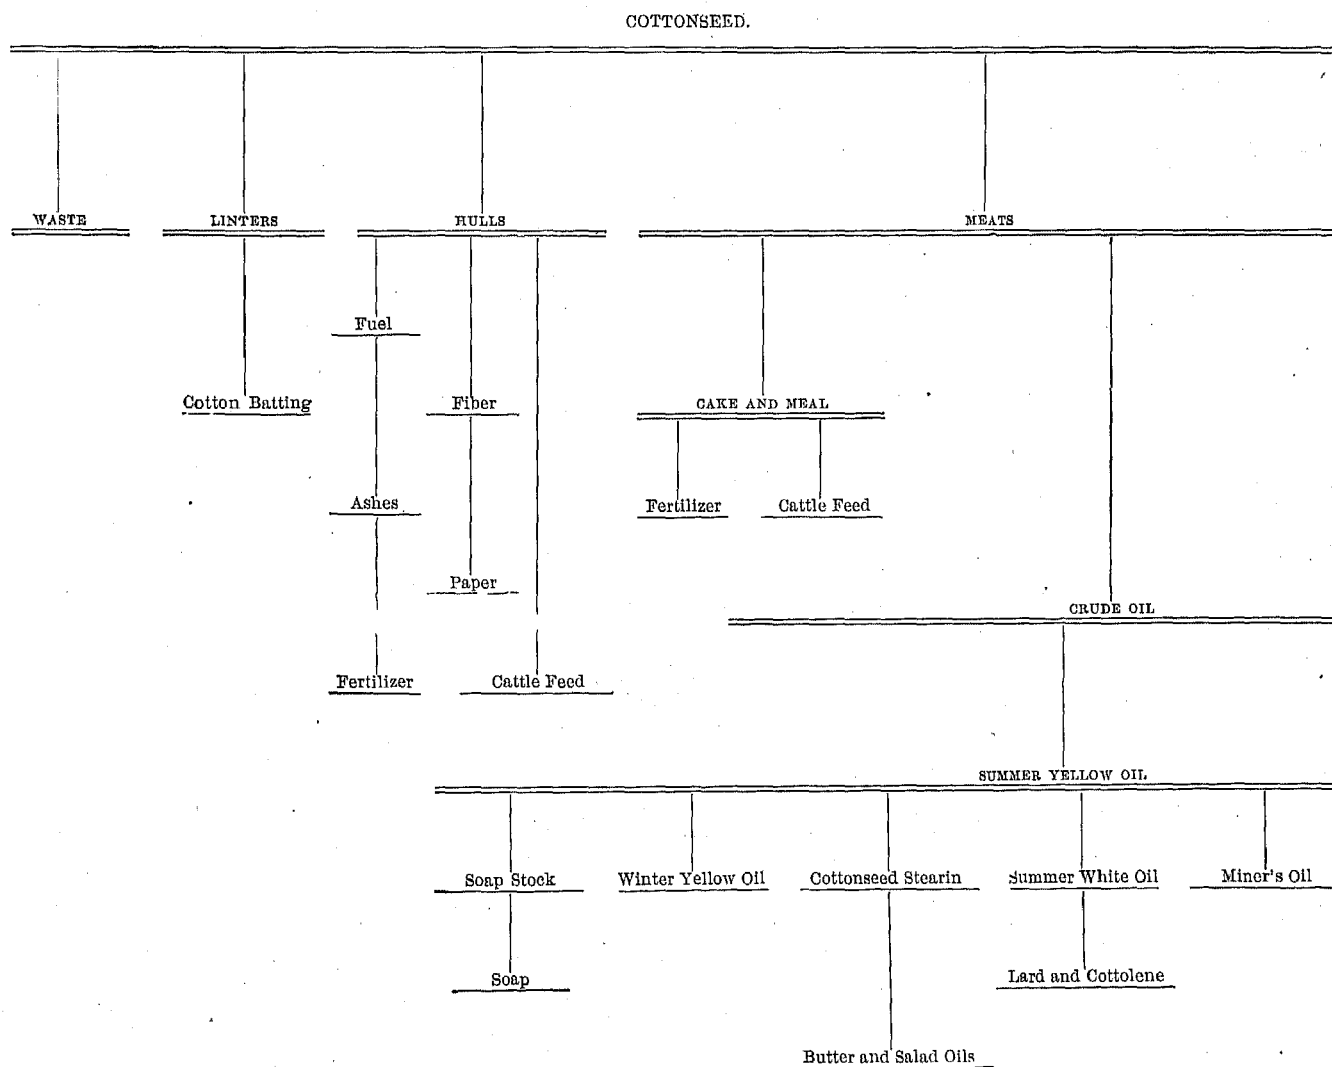

**OIL.**—The most valuable and by far the most interesting product of cottonseed is oil. The quantity

obtainable from a ton of seed varies with the natural condition of the seed, the manner in which it is cared for, and the character of the machinery by which it is treated. Among the reports made to the Census Office a range of from twenty-five to fifty gallons per ton is given; for the United States, as shown in Table 2, there was an average of 37.6 gallons per ton. Actual analysis shows a proportion of somewhat more than fifty gallons of oil per ton of seed, and it would appear that through improved machinery this maximum quantity is rapidly being attained.

In the beginning of the industry cottonseed oil was looked upon only as an adulterant, and was used principally in Holland, Italy, and France. This source of demand still exists, but the oil is rapidly gaining ground upon its own merits. Its edibility is the basis of its value, and when it falls below the standard in this particular it must command lower prices.

The several products that may be derived from a given quantity of cottonseed are presented in the following diagram:

DIAGRAM SHOWING PRODUCTS OBTAINABLE FROM COTTONSEED.

The above diagram illustrates the history of a given quantity of cottonseed from the time it reaches the oil mill until it is separated into products, such as fertilizers, lint, cattle feed, paper stock, and oils adapted to various uses.

As appears from this diagram, the oil resulting from the first refining process is known in commerce as "summer yellow oil," and is classed by the trade as "prime" when it is entirely free from water, sediment, and alkali.

The next step is to get what is called "winter yellow oil," obtained by chilling the "summer yellow oil" until it is partially crystallized, and by separating the stearin in presses. This latter product is utilized in making "butter and salad oils" and candles.

"Summer yellow oil," thoroughly mixed with 2 to 3 per cent of fuller's earth and filtered, yields the next grade of oil, which is known in commerce as "summer white oil," from which is obtained "compound" lard and cottolene.

"Miner's oil" is a white oil secured from the "summer yellow oil" by the use of sulphuric acid, and is mixed with petroleum for use in miners' lamps.

Soap stock is the residue obtained from the refining processes. It contains from 50 to 60 per cent of fatty acids and is used in making soaps. Mixed with other greases, this stock makes one of the finest grades of laundry soap. It is also utilized in making cylinders for phonographs.

Experiments with cottonseed oil as an adulterant of linseed oil for paints and for lubricants have not been attended with much success. In the case of linseed oil this is due to the failure to supply the necessary drying qualities. As a lubricant it has been excluded on account of its gummy nature, except for the most ordinary purposes. Some success has attended experiments for the removal of the gum and its use as a substitute for rubber, leaving the oil capable of use as a lubricant.

Prejudice against the use of cottonseed oil in the preparation of foods is gradually growing less, a fact vividly illustrated by the following excerpt:

If the outsider does not know that olive oil has a legitimate and a strong competitor in cotton oil, the olive grower knows it. He

knows it as a hard commercial fact, as the truth has been driven right into his pocketbook.

"France is really the home of the olive grove. In southern France the farmers are disposed to abandon the cultivation of olive groves," writes Consul Skinner, from Marseilles, "because of low and unsatisfactory prices." After a careful investigation of the field our consul makes the following startling statements as to olive oil and the European taste for it:

"It is doubtful if olive oil will ever recover its old-time place, as many vegetable oils, notably American cottonseed oil, are being produced in increased quantities from year to year, and are gaining in the estimation of the public.

"Pure olive oil for edible purposes is at present practically unknown in any important market, and if it were offered for sale it is doubtful whether it would be accepted by the public, except as an inferior article, as the average consumer at the present time prefers the neutralized taste of a mixture of the olive and vegetable oils, and would mistake the fruity flavor of the pure juice of the olive for an adulterated product."

If the producers of olive oil have really recognized the superior merits of cotton oil, why should we be so particular about the oil of olives? This transition of taste and gravitation of trade from the olive to the cotton product doubtless led France to her recent extraordinary legislation in favor of French makes of cotton oil for blending purposes.<sup>1</sup>

In some localities competition for seed among the mills is already affecting the percentage of profit of mills operated only for crude products. As the total quantity of seed crushed approaches the quantity available, the cost of the seed will tend to increase and to cause the equipment of more oil refineries in connection with the oil mills, in order to secure for their products all that the market will permit. The advantage of small refineries in connection with the cottonseed-oil plants is illustrated by the following comparison:<sup>2</sup>

<i>Crude products only.</i>		<i>Crude and refined products.</i>	
Cost of seed.....	\$12.00	Cost of seed.....	\$12.00
Cost of operation.....	3.00	Cost of operation.....	20.00

ALCOHOLIC LIQUORS.

---

(595)

# ALCOHOLIC LIQUORS.

By JOHN H. GARBER.

Alcohol is a natural product derived from sugar in the process of alcoholic fermentation. Wine is the simplest and its manufacture the least complex of all alcoholic liquors, as it consists of fruit juices whose saccharine matter is converted into alcohol on exposure to the air. The manufacture of malt liquors is more complex, as it involves the preliminary process of malting, by which the starch of grains is converted into sugar, which in turn is converted into alcohol by fermentation. Alcohol being produced by fermentation is found in dilute form mingled with other liquids and the manufacture of distillates is the additional process of separating it, more or less completely, from the mixture. As the various liquids vaporize at different temperatures, the separation is effected by the application of such degree of heat as will vaporize the alcohol out of its combinations.

For the collection of statistical data pertaining to the manufacture of alcoholic liquors the Census Office divided them into three classes, namely: Malt liquors, embracing beers, ales, porters, and all similar beverages fermented from malt infusions and included in the products of the brewing industry; distilled liquors, embracing all ardent spirits separated by distillation from fermented fruit juices, molasses, or malt infusions of grain; and vinous liquors, embracing all varieties of wines fermented from the juice of grapes and berries. From the reports of breweries, distilleries, and wineries, representing the three classes of alcoholic liquors, statistics of which are herewith presented in detail, it appears that 1,198,602,104 gallons of malt liquors, 103,330,423 gallons of distillates, and 23,425,567 gallons of wine were manufactured during the census year ending May 31, 1900. This is a total for all classes of 1,325,358,094 gallons, which does not include quantities reported from small establishments with a product less than \$500 each; wine returned from farms and as a subsidiary product of distilleries; and spirits returned from wineries, principally as a by-product. In estimating the annual consumption for 1900, the quantity of tax-paid spirits, not the quantity manufactured, was employed, and the differences between imports and domestic and foreign exports were considered. On this basis the total estimated consumption for the census year was 1,322,166,685 gallons, or 17.3 gallons per capita.

The totals for the three classes show 2,835 establishments, with a capital of \$457,674,087, and products valued at \$340,615,466. This last amount includes \$96,798,443 as the value of distilled liquors, which includes an indeterminate amount of internal-revenue tax, because of a lack of uniformity in reporting it. If

such tax were included in every instance, the value of the distillates reported would approximate \$140,000,000 and the total value of all liquors would be increased from \$340,615,466 to about \$384,000,000. Returns from breweries uniformly included internal-revenue tax in values of products.

Malting, bottling, and the manufacture of mineral and soda waters, while not presented in detail in this report, are, in their relation to the manufacture of alcoholic liquors, correlative industries. At the census of 1900, the malting industry showed 146 establishments, with \$39,288,102 capital, 1,990 wage-earners, \$14,816,741 for cost of materials, and products valued at \$19,373,600; the bottling industry, 2,064 establishments, with \$16,620,152 capital, 7,680 wage-earners, \$28,087,823 for cost of materials, and products valued at \$41,640,672; and the manufacture of mineral and soda waters, 2,816 establishments, with \$20,518,708 capital, 8,985 wage-earners, \$8,801,467 for cost of materials, and products valued at \$23,874,429. The malt reported by the maltsters was very largely manufactured into malted beverages, and a large proportion of the independent bottling plants were bottlers of malt liquors and whiskies purchased from brewers and distillers. The totals given for the value of products for these two industries are, therefore, to a considerable extent, duplications of the corresponding totals for alcoholic liquors.

Table 1 shows the combined totals for the three classes of alcoholic liquors and the corresponding totals for each class.

TABLE 1.—ALCOHOLIC LIQUORS: SUMMARY, 1900.

## THE MANUFACTURE OF MALT LIQUORS.

In colonial times, as well as in the early decades of the nation's history, the consumption of malt liquors was relatively small and increased slowly. The wide distribution of small quantities of wine manufactured from grapes or currants, the introduction of tea, the general consumption of all classes of distilled spirits, and the household manufacture of cider and fruit brandies satisfied the tastes of the people, and the demand for malt liquors was of slow and gradual development. Where the demand existed at all it was

for ale, porter, or stout. The manufacture of lager beer in the United States was begun about 1840. Its use extended with the general increase of population, the influx of German immigrants, and the cultivation of the tastes of the people for milder beverages. In 1900 its use had almost entirely superseded that of ale and porter.

Table 3 is a comparative summary of statistics of the manufacture of malt liquors as returned at the censuses of 1850 to 1900, inclusive, with the percentages of increase for each decade.

TABLE 3.—LIQUORS, MALT: COMPARATIVE SUMMARY, 1850 TO 1900, WITH PER CENT OF INCREASE FOR EACH DECADE.

<sup>1</sup> Decrease.

<sup>2</sup> Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 9.)

<sup>3</sup> Not reported separately.

<sup>4</sup> Not reported.

Table 3 shows that the brewing industry for the last half century has had practically an uninterrupted growth. In the percentages of increase or decrease for the different decades, a decrease is shown in but two instances, viz., in the number of establishments from 1880 to 1890, and in the cost of materials from 1890 to 1900. From 1880 to 1890 the number of establishments decreased 943, or 43 per cent, and from 1890 to 1900 increased 261, or 20.9 per cent. The net decrease in the twenty years from 1880 to 1900 was 682, or 31.1 per cent, which was largely due to consolidations of brewing interests and the lack of uniformity in reporting the number of establishments included in such consolidations. The decrease in cost of materials was due to the lower prices of barley, hops, and corn, prevailing in 1900 as compared with 1890, and to the introduction of improved methods of manufacture, which brought about a more thorough extraction and use of the productive elements of materials. The introduction of improved and economic methods of refrigeration, while adding largely to the capital of the industry, also aided very materially in reducing cost of production.

The decrease of 19.3 per cent in cost of materials from 1890 to 1900 was accompanied by an increase of 29.8 per cent in value of products. This discrepancy is much

more apparent than real, since in 1900 the value of malt liquors included the increased cost of the internal-revenue stamps required under the war tax then in effect. If the net price of the product had been reported—i. e., the price less the internal-revenue tax—the percentage of increase for 1900 would approximate 5.4 per cent instead of 29.8 per cent, and the apparent discrepancy between the percentages of change in cost of materials and value of products would disappear.

Miscellaneous expenses increased \$61,052,941, or 126.5 per cent, in the decade from 1890 to 1900. This disproportionate increase was due to the same circumstances noted above—the increase in internal-revenue tax, which was one of the items of miscellaneous expense. In 1890 the net tax on malt liquors was 92½ cents, and in 1900, \$1.85 per barrel. The amount of revenue tax paid in 1900 exceeded that paid in 1890 by approximately \$47,000,000, leaving an increase of \$14,000,000, or 29.1 per cent, in the other items of miscellaneous expense.

In the half century closing with 1900 the industry increased in number of establishments from 431 to 1,509; in capital, from \$4,072,380 to \$415,284,468; in number of wage-earners, from 2,347 to 39,532; in wages, from \$654,144 to \$25,826,211; and in value of products from \$5,728,568 to \$237,269,713.

## MANUFACTURES.

Table 4 shows the comparative distribution of capital for 1890 and 1900.

TABLE 4.—LIQUORS, MALT: COMPARATIVE SUMMARY, CAPITAL, 1890 AND 1900.

	1900	1890	Per cent of increase.
Total .....	\$415,284,468	\$232,471,290	78.6
Land .....	53,611,097	33,538,926	59.8
Buildings .....	119,232,506	64,412,133	85.1
Machinery, tools, and implements.....	76,398,777	50,288,210	51.9
Cash and sundries.....	166,042,088	84,232,021	97.1

Table 4 shows that at the census of 1900 the capital amounted to \$415,284,468, an increase of \$182,813,178, or 78.6 per cent, for the decade. This amount was distributed as follows: Land, \$53,611,097; buildings, \$119,232,506; machinery, tools, and implements, \$76,398,777; and cash and sundries, \$166,042,088. Of the four divisions of capital, cash and sundries shows

the largest percentage of increase; this division includes cash on hand, bills receivable, unsettled ledger accounts, raw materials, stock in process of manufacture, finished products on hand, and other sundries. In 1900 the amount reported for these items was \$166,042,088, and in 1890, \$84,232,021, an increase of \$81,810,067, or 97.1 per cent. This relatively higher rate of increase is in part due to the greater cost of internal-revenue stamps carried on hand and in part to the increased facilities made necessary by the expansion of an industry in which competition is active.

Table 4 does not include, for 1900, 16 idle establishments, with a capital of \$945,577, and 15 active establishments, each with a product less than \$500, with a capital of \$30,965. The combined capital of these two classes of establishments was \$976,542, making an aggregate capital for the industry of \$416,261,010.

Table 5 is a comparative summary, by states and territories, of the principal statistics of the industry for the censuses of 1890 and 1900.

<sup>1</sup>Included in "all other states."

<sup>2</sup>Includes establishments distributed as follows: Arkansas, 1; Florida, 1; Kansas, 2; South Carolina, 1.

<sup>3</sup>Includes establishments distributed as follows: Nevada, 2; New Hampshire, 1; New Mexico, 2; North Dakota, 1; South Carolina, 1; South Dakota, 1; Wyoming, 2.

This table shows a wider distribution for the manufacture of malt liquors than is shown by the corresponding tables of this report for the manufacture of either distillates or wine. Commercial wine making is necessarily localized where soil and climatic conditions will produce the desired varieties of grapes. The manufacture of distilled liquors from grain, owing to the fact that the finished product is less bulky than the raw material, and consequently costs less to transport, tends to localize at points where the cereal supply is ample and its cost least. This is particularly true of the manufacture of alcohol and pure, neutral, or cologne spirits. In the manufacture of malt liquors the transportation of the finished product involves greater expense than that of the materials used, and the industry tends to localize at points of consumption. There are a few large establishments, however, with an output ranging from 500,000 to 1,000,000 barrels a year, and whose products have a wide distribution, to which

this law does not now apply, although it governed their inception and influenced their early history. At the census of 1900, 38 states and territories reported a total of 1,504 establishments out of 1,509 for the United States, and practically every state showed a substantial increase in value of products, the three notable exceptions being Louisiana, Maryland, and Missouri.

The leading states in value of malt liquors produced during the census year were as follows: New York, \$56,137,854; Pennsylvania, \$29,162,743; Illinois, \$19,733,821; Wisconsin, \$19,394,709; Ohio, \$18,522,639; New Jersey, \$14,386,456; and Missouri, \$13,776,905. From Table 9 it appears that the quantity produced in each of the same states was as follows: New York, 9,593,085 barrels; Pennsylvania, 4,648,172; Illinois, 3,794,782; Wisconsin, 3,049,191; Ohio, 3,028,116; Missouri, 2,410,999; and New Jersey, 2,117,491.

Table 6 shows the quantity and cost of materials and the quantity and value of products for 1900.

Beer, ale, and porter.	Barrels of 31 gallons.	38,664,584		234,275,259
All other products.				2,994,454

It appears from Table 6 that there were manufactured during the census year, 38,664,584 barrels of malt liquors, valued at \$234,275,259, or an average of \$6.06 a barrel. This represents the value of the product at the brewery, packed in barrels, kegs, or bottles, and ready for shipment, with the necessary revenue stamps affixed. This table shows also that 36,385,365 bushels of malt, 11,232,599 bushels of barley, 37,465,811 pounds of hops, and 483,998,984 pounds of corn were the principal materials used in the production. In addition there were consumed and reported under "all other materials" considerable quantities of rice, sirup, glucose, and similar ingredients. With the 11,232,599 bushels of barley converted into malt, the approximate average quantities of the principal ingredients consumed in producing a barrel of beer were 1½ bushels of malt, 1 pound of hops, and 12 pounds of corn. The corn was used in the form of meal and grits of varying degrees of coarseness, or in the form of cerealine (flakes) or maizone. The hops used ranged in quality from the cheapest domestic product to the finest Bohemian importation.

Table 7, taken from the annual report of the Commissioner of Internal Revenue for the fiscal year 1900, shows the quantity of malt liquors manufactured in the United States for each fiscal year from 1863 to 1900, inclusive.

TABLE 7.—LIQUORS, MALT: QUANTITY MANUFACTURED IN EACH FISCAL YEAR FROM 1863 TO 1900.

YEAR.	Number of barrels.	YEAR.	Number of barrels.
1863	2,006,625	1882	16,952,085

1870	6,574,617	1889	25,119,853
1871	7,740,260	1890	27,561,944
1872	8,659,427	1891	30,478,192
1873	9,633,323	1892	31,817,836
1874	9,600,897	1893	34,554,317
1875	9,452,697	1894	33,334,733
1876	9,902,352	1895	33,561,411
1877	9,810,060	1896	35,826,098
1878	10,241,471	1897	34,428,094
1879	11,108,084	1898	37,493,306
1880	13,347,111	1899	36,581,114
1881	14,311,028	1900	39,330,849

Table 7 shows 39,330,849 barrels reported to the Internal-Revenue Bureau for the fiscal year ending June 30, 1900, as against 38,664,584 reported to the Census Office for the census year ending May 31, 1900. The census tabulation does not include 15 breweries, each with a product less than \$500, whose combined product was 3,896 barrels; and a number of small establishments, principally producers of weiss beer, which were not reported. With these items considered, and also the difference in time covered by the two reports, the figures of the Internal-Revenue and Census bureaus practically agree.

The 38,664,584 barrels reported at the census of 1900 were equivalent to 1,193,602,104 gallons. In computing per capita consumption, malt liquors, because of the comparatively short time necessary to prepare them for market, do not present the difficulties common to wines and distillates, which require longer time for aging. Beer is the product of a slow fermentation and some few months are necessary to mature it properly, but there is practical uniformity in the quantities carried over from year to year, and the annual production, less the excess of exports over imports, practically represents the annual consumption. During the fiscal year ending June 30, 1900, 5,496,131 gallons were exported, and during the same period 3,310,320 gallons were imported, of which 7,841 gallons were exported, leaving 3,302,479 gallons imported for domestic consumption, an excess of exports over net imports of 2,193,652 gallons. This quantity, subtracted from the total production, leaves 1,196,408,452 for annual consumption in the United States, or 15.7 gallons per capita.

Table 8 shows the quantity, value, and destination of malt liquors exported during the fiscal year 1900.

Turkey in Africa—Egypt.....	1,600	2,148		

It appears from Table 8 that, while the exports had a wide distribution among the countries of the world, the sales were, as a general rule, small and unimportant. The largest shipments were consigned to the countries recently acquired or occupied by the United States, viz., Hawaii, Cuba, and the Philippine Islands.

Table 9 shows the detailed statistics, by states and territories, of the manufacture of malt liquors.

<sup>1</sup> Decrease.

<sup>2</sup> Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 16.)

<sup>3</sup> Not reported separately.

<sup>4</sup> Not reported.

As a rule, statistical inquiries of the Census Office pertaining to the value of manufactures contemplate value of products at factories, put up in marketable form and ready for shipment. If this principle were uniformly observed, the value of distillates would be placed upon them when in barrels, kegs, or other packages, with the necessary revenue stamps affixed, so that such value would always include the revenue tax. The values of products at different censuses would then be difficult to compare, because the tax varies with each legislative enactment. Since 1865 the tax on each proof gallon of distilled spirits has varied from 50 cents to \$2, or from two to six times the value of the spirits alone.

The revenue, however, is not always included in

reporting values. Distillers of grain or molasses must, in accordance with Government regulations, provide warehouses for their products. These are known as bonded warehouses, and are in charge of bonded officers of the Government. All spirits produced from molasses or grain must, before shipment, be placed in warehouses for record, even though they be alcohol, cologne spirits, or other classes that do not require aging and are immediately marketable; all whiskies that require aging are allowed by the Government to remain in bonded warehouses for a maximum period of eight years and no tax is collected until the whiskies are withdrawn. For this reason the quantity of spirits withdrawn for consumption and export in any year may be much less

or much more than the quantity deposited or manufactured during the same period, and may include a fraction of the quantity manufactured within each of the preceding eight years. As no fixed law governs the length of time whiskies remain in bond, the amount of revenue annually collected bears no fixed relation to the quantity of whisky concurrently manufactured, and is, therefore, indeterminate as a factor of value.

The manufacturers of alcohol, cologne spirits, and such other classes as do not require aging, reported the value of their products to the Census Office as including the revenue tax, while among manufacturers of whisky there was no uniform practice in this respect. A trade custom has grown up under which distillers of whisky seldom pay excise tax to the Government. They receive orders from purchasers in advance of manufacture. The orders are booked, filled in turn, the spirits warehoused, and the purchaser furnished a warehouse receipt, on which he makes payment to the distiller exclusive of revenue. The purchaser pays the tax when he withdraws the whisky from bond. Some manufacturers of whisky, in reporting their operations to the Census Office, computed revenue on their entire output, while others excluded it altogether; still others reported only what they actually paid on their own withdrawals during the census year.

It is not possible, in consideration of the practices above described, to determine with exactness the amount of tax included in the \$96,798,443 reported as the value of the 103,330,423 gallons of spirits produced in 1900, on which the revenue alone, if all computed, would amount to \$113,663,465. The value of the 103,330,423 gallons would, if all were tax-paid, approximate \$140,000,000. The records of the Bureau of Internal Revenue show that in 1890, 111,101,738 gallons of spirits were manufactured, and in 1900, 109,245,187 gallons. In 1890, \$76,539,003 in taxes were collected on 85,043,336 gallons of spirits, and in 1900, \$104,375,921 were collected on 94,887,201 gallons. Evidently, therefore, the \$104,197,869 reported as the value of products in 1890 includes a much greater proportion of revenue than the \$96,798,443 reported for value of products in 1900. The \$73,218,227 reported for miscellaneous expenses at the census of 1900 includes only such revenue as is also included in the \$96,798,443 reported as the value of products, and the two amounts are, therefore, in correct proportion.

Prior to 1870 the factor of internal-revenue tax is not included in value of products as shown in Table 10. Excise taxes have followed the three principal wars of the United States, viz., the Revolutionary War, the War of 1812, and the Civil War. The first law went into effect in 1791 and continued in operation until the accession of President Jefferson, on whose recommendation it was repealed. The second law was enacted in 1813, and repealed in 1817 on the recommendation of President Monroe. The present system of internal taxation was established in 1862 and, with

modifications, has remained constantly in force. Since that date statistics of the production of distilled and malt liquors have been more complete and reliable than formerly. For the fiscal year 1870, 72,560,929 gallons of spirits were manufactured, and taxes were paid on 78,490,198 gallons, yielding \$39,245,099 revenue. In 1880, 91,378,417 gallons were manufactured, and taxes were paid on 62,132,415 gallons, contributing \$55,919,119 to the revenue of the Government. The amounts shown in Table 10, as the value of products for those years, are \$36,191,133 and \$41,063,663, respectively, or less in each case than the amount of the internal-revenue tax collected. Judging from the quantities of spirits manufactured in those years, the values reported can include only a small portion of the excise tax.

As an industry the manufacture of distilled spirits is subject to many vicissitudes and undergoes curious modifications. In the settlement of a new country it tends to diffuse among the people in the form of numerous small distilleries, increasing the number of establishments without a proportionate increase of capital or output. Such establishments produce whiskies and brandies. In older portions of the country, where trade customs are more permanently fixed, and supply and demand approach nearer to a mathematical certainty, the industry tends to centralize into large establishments.

This is shown by the fluctuations in number of establishments and by the varying relations between them and the average number of wage-earners. In 1850, 968 establishments employed 4,008 wage-earners, or 4.1 each; in 1860, the corresponding figures were 1,215 and 5,624, or 4.6 wage-earners to each establishment; in 1870, 719 and 5,131, or 7.1 each; in 1880, 844 and 6,502, or 7.7 each; in 1890, 440 and 4,762, or 10.8 each. In 1900 the number of establishments had increased to 967, but statistics of wage-earners for 1900 are not comparable with previous censuses, as explained elsewhere.

In spite of the fluctuations in numbers of establishments and of wage-earners from decade to decade, the reports at successive censuses show a continuous increase in capital. In 1870 this increase, concurrent with a decrease in number of establishments and wage-earners, was mostly due to the fact that values were reported in a depreciated currency, the average value of the dollar for that year being 79.81 cents gold.

It seems that the census of 1890 concerned itself only with the largest and most important establishments, and considered each combination of distilleries operated by the same corporation as one establishment. It appears, too, that the very small fruit and grain distilleries distributed in great number through the Southern states, especially Virginia and North Carolina, were much more thoroughly canvassed in 1900 than in 1890. These facts explain the disproportionate increase in number of establishments during the last decade, as shown by Table 10.

The report of the Commissioner of Internal Revenue for the fiscal year ending June 30, 1900—a month later than the census year—shows that a total of 3,614 distil-

leries were operated within that year. Of these, 10 were given over to the distillation of molasses, 1,304 to grain, and 2,300 to fruit.<sup>1</sup> At the census of 1900, 646 small distilleries, each with an output less than \$500 in value, were reported and not included in the 967 establishments shown in Table 10. These small distilleries reported 47 wage-earners, \$6,505 wages, \$142,709 capital, and products valued at \$108,048. The 2,001 establishments of this class from which reports were not received by the Census Office in 1900 are of little consequence, except to the student of purely local statistics. As a rule they are operated but a few days in the autumn of each year, and the same still may be made to do service on several farms in the same season. The output in each case usually consists of a small quantity of fruit brandy. The entire capital is but a few dollars, invested in a still set up by a spring of water, and no building or land values are involved.

Table 11 shows the four divisions of capital for the censuses of 1890 and 1900, with the percentages of increase or decrease for the decade between.

TABLE 11.—LIQUORS, DISTILLED: COMPARATIVE SUMMARY, CAPITAL, 1890 AND 1900.

	1900	1890	Per cent of increase.
Total .....	\$32,551,604	\$31,006,176	5.0
Land .....	2,524,480	2,816,967	<sup>2</sup> 10.4
Buildings .....	6,430,565	6,299,511	2.1
Machinery, tools, and implements.....	7,535,050	7,856,249	<sup>2</sup> 4.1
Cash and sundries.....	16,061,509	14,033,449	<sup>2</sup> 14.5

<sup>1</sup> Report Internal Revenue Commissioner, 1900, page 96.  
<sup>2</sup> Decrease.

The total capital for 1900 shown by this table is identical with the item of capital in Table 10, and is repeated to show its divisions, which are: Land, \$2,524,480; buildings, \$6,430,565; machinery, tools, and implements, \$7,535,050; and cash and sundries, \$16,061,509. This last item includes cash on hand, bills receivable, unsettled ledger accounts, raw materials, stock in process of manufacture, finished products on hand, and other sundries. On June 30, 1900, however, there were 136,071,880 gallons of manufactured spirits in bonded warehouses,<sup>1</sup> and it is evident that only a very small part of such quantity could have been reported as owned by distillers and included by them in the \$16,061,509 reported for cash and sundries. From 1890 to 1900, an increase of 5 per cent is shown for total capital, 2.1 per cent for buildings, and 14.5 per cent for cash and sundries. A decrease of 10.4 per cent is shown for land, and 4.1 per cent for machinery, tools, and implements. This seeming inconsistency is due to the policy of large combinations of capital in localizing the manufacture of certain classes of distillates at points favoring least cost of production, and closing several large plants at other points. At the census of 1900, 110 idle establishments were reported, with a total capital of \$3,633,910, which is not included in Table 11. At the active plants, buildings were improved on less expensive grounds, and machinery and equipment were brought nearer to the limit of their capacity.

Table 12 is a comparative summary of the industry, by states and territories, for 1890 and 1900.

<sup>1</sup> Report Internal Revenue Commissioner, 1900, page 149.

<sup>1</sup> Included in "all other states."

<sup>2</sup> Includes establishments distributed as follows: Idaho, 1; Louisiana, 1; Nebraska, 2; New Hampshire, 1.

<sup>3</sup> Includes establishments distributed as follows: Minnesota, 2; Nebraska, 1; Texas, 2; Washington, 2; West Virginia, 2; Wisconsin, 2.

Of the 967 establishments reported at the census of 1900, 962 were returned from 23 states and 1 territory. The remaining 5 were distributed among 4 states. Twenty-seven states and 1 territory are, therefore, represented in the above table. The unusually thorough canvass of small distilleries for the census of 1900, and the lack of uniformity in including internal-revenue tax in reporting values, should be considered in making comparisons; these considerations will explain most of the seeming inconsistencies in Table 12. In some of the states, however, the decline shown is due to causes common to all classes of trade, and to changes in local liquor laws; in others it is due to the policy of corporations in closing establishments at certain points to concentrate manufacturing operations.

Illinois, with an output of 32,508,435 gallons of spirits, was the leading producer in 1900. Kentucky ranked second, with 21,709,873 gallons, and Indiana, Ohio, Pennsylvania, and Maryland followed in the order named with 17,494,779, 9,518,850, 7,189,655, and 3,812,856 gallons, respectively. In Illinois the industry is concentrated into a few large establishments, located principally in the city of Peoria, while in Kentucky it is well diffused. This in part explains the difference in capital reported from those two states. North Carolina, with the very small output of 599,540 gallons of spirits, was the leading state in number of establishments.

Table 13 shows the quantity and cost of materials and

the quantity and value of products for the manufacture of distilled liquors in 1900.

TABLE 13.—LIQUORS, DISTILLED: MATERIALS AND PRODUCTS, 1900.

According to this table, the total quantity of all classes of distilled spirits reported at the census of 1900 was 103,330,423 gallons, which does not include the output of 2 large establishments in the state of New York (closed when the canvass was made); 102,028 gallons reported from 646 establishments, each with an output less than \$500 in value; brandy used in the for-

tification of wines; and the output of about 2,000 small fruit distilleries from which reports were not sought. The combined quantity used for fortification and that not reported from New York approximates 4,000,000 gallons, making a total of more than 107,000,000 gallons identified by the Census Office. The comparatively small difference between this quantity and the 109,245,187 gallons reported to the Internal Revenue Bureau for the fiscal year ending June 30, 1900, is due to the different periods covered by the reports of the two bureaus and to the product of the 2,000 small establishments not canvassed by the Census Office.

Table 13 shows that a total of 24,258,500 bushels of grain, 1,339,606 gallons of wine, 2,962,691 gallons of molasses, and fruit (quantity not ascertained) costing \$256,551, were used in manufacturing 103,330,423 gallons of spirits. It is not possible to reduce these quantities to correct equivalents, because of the lack of uniformity in the use of particular materials for particular products. Generally speaking, grain is used in the manufacture of gin, whisky, alcohol, and cologne spirits; fruit and wine in the manufacture of brandy; and molasses in the distillation of rum. According to this practice, 24,258,500 bushels of grain were used in the distillation of 100,875,666 gallons of gin, whisky, alcohol, and cologne spirits, or an average of 4.16 gallons of spirits for each bushel of grain. Wheat is little used because of its greater cost, and corn is largely used because of its cheapness. Of the total quantity of grain consumed, 68.2 per cent was corn. It is made into corn whisky, Bourbon whisky, alcohol, and neutral or cologne spirits. The 1,546,706 gallons of rum reported do not represent the quantity distilled from 2,962,691 gallons of molasses, as a part of the molasses reported was manufactured into pure spirits.

The determination to make, for the first time, the manufacture of alcoholic liquors the subject of special inquiry, was reached too late in the organization of the Census Office work to permit the drafting of special schedules designed to secure accurate data pertaining to the different classes of liquors. The reports of the several establishments were made on the general schedule for manufactures. The inquiries sought to elicit accurate statistics of the total quantity of spirits manufactured, but the importance of the several classes could not be emphasized. No great accuracy, therefore, is claimed for the classification of products as shown in Table 13. It is possible that the 54,304,925 gallons reported as alcohol and cologne spirits, and the 45,483,592 reported as whisky, both include some spirits that should receive a more definite classification. The distillation of alcohol and pure, neutral, or cologne spirits is largely confined to the states of Illinois and Indiana; that of Bourbon whisky to Kentucky; and that of rye whisky to Pennsylvania and Maryland.

Table 14 shows the quantity of distilled spirits manufactured and also the quantity on which revenue tax was paid, by fiscal years, from 1863 to 1900, inclusive.<sup>1</sup>

<sup>1</sup>Report of Commissioner of Internal Revenue, 1900, pages 440 and 441.

1881.....	119,528,011	69,127,206	1900.....	109,245,187	94,887,201

An examination of this table shows that for a series of years the quantity of spirits manufactured fluctuates considerably more than the quantity withdrawn from bond, or tax paid. In 1881, 119,528,011 gallons, and in 1882, 107,283,215 gallons were distilled; in 1883 the quantity was but 75,294,510 gallons. The largest quantity manufactured in any year was 131,010,330 gallons, in 1893. In the succeeding year, 1894, only 92,163,651 gallons were produced. The quantities withdrawn and tax paid for the same years show more uniformity, and are more nearly representative of the annual consumption.

During the fiscal year ending June 30, 1900, internal-revenue tax was paid on 94,887,201 proof gallons of spirits, presumably withdrawn for consumption. In the same period 2,482,020 gallons were imported, of which 46,767 gallons were exported, leaving 2,435,253 gallons as the net imports for domestic consumption. This is an excess of 551,648 gallons over domestic exports, which amounted to 1,883,605 gallons.

A large quantity of distilled spirits is annually consumed in the arts and sciences, and in compounds and manufactures of medicines. At the census of 1890 this was reported as 10,976,842 gallons. At the census of 1900 no special inquiry was made as to the quantity so used, but it may safely be estimated to have exceeded the quantity consumed in 1890.

The output of illicit distilleries is large, but of course can not be estimated. The increase in volume of spirits passing through rectifying houses should also be considered in computing per capita consumption. With these various items taken into account it appears that the quantity consumed as a beverage by the people of the United States during 1900 could not have been far from 91,000,000 gallons, or a per capita consumption of approximately 1.2 gallons. Most of the distilled liquors consumed as a beverage by the American people pass through rectifying houses. The different classes of rectified spirits range from the cheapest concoctions of neutral spirits and drugs to the simple

ALCOHOLIC LIQUORS.

blending of young and old whiskies. The number of gallons rectified in the United States during 1900 was 74,508,420.

Table 15 shows the quantity, value, and destination of distilled liquors exported from the United States during the fiscal year ending June 30, 1900.

<sup>1</sup> Decrease.

<sup>2</sup> Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 22.)

<sup>3</sup> Not reported separately

<sup>4</sup> Not reported.

The decade closing with 1860 witnessed the birth of commercial wine manufacture in the United States. The experiments of Nicholas Longworth at Cincinnati, Ohio, hereinafter referred to, were followed by the development of wine manufacture in the Hudson River Valley and the lake districts of New York, and in the Lake Erie district, comprising the southern shore of that lake and adjacent islands. At the census of 1860 California, New York, and Ohio were the leading three states in wine production. In 1870 the wine product of Missouri exceeded that of any other state, and in 1890 exceeded that of New York, though not that of California. With these exceptions, California, New York, and Ohio have been throughout the leading states in this industry. In 1900 their combined output was 22,404,085 gallons of wine, out of a total of 23,425,567 gallons for the United States.

From Table 17 it appears that while the industry made rapid progress from 1860 to 1870, in the succeeding ten years, from 1870 to 1880, there was a decrease in number of establishments of 281, or 70.6 per cent; in average number of wage-earners of 519, or 34.9 per cent; and in value of products of \$56,045, or 2.5 per cent. During this decade a substantial increase in the industry was shown in Ohio and New York, and the decline for the entire United States, shown by the table, was chiefly due to conditions in the states of California and Missouri. Between 1870 and 1875 an enthusiastic interest in viniculture spread over California, resulting in a great increase in the acreage of vineyards. This caused an overproduction of wine, which was followed by ruinous depreciation in prices, entailing heavy losses to all classes of producers. Many vineyards were uprooted and the land given over to other lines of horticulture. In 1870 California reported 139 establishments, and in 1880 only 45.

The large producers, however, as a rule had faith in the future, and continued to improve their properties, so that capital for the decade ending with 1880 showed a decline of only \$18,820, or 2.9 per cent for the state, while there was an increase for the United States of \$247,516, or 10.6 per cent. By 1879, as a result of the widening market for California wines, consumption had overtaken production and prices advanced, so that in 1880, notwithstanding the depreciation experienced during a portion of the decade, statistics for the state show a slight increase in value of products. The decline from \$2,225,238 to \$2,169,193 in the value of products for the United States was largely due to the general depression of the industry in Missouri, caused by the blight which greatly injured the grape crops of the state. Since 1880 the progress of wine manufacture in the United States has been continuous. During the forty years ending with 1900 the industry increased in number of establishments from 32 to 359; in capital, from \$306,300 to \$9,838,015; in number of wage-earners, from 106 to 1,163; in wages, from \$43,208 to \$446,055; and in value of products, from \$400,791 to \$6,547,310.

Table 18 is a comparison of the several items of capital as reported at the censuses of 1890 and 1900.

TABLE 18.—LIQUORS, VINOUS: COMPARATIVE SUMMARY, CAPITAL, 1890 AND 1900.

	1900	1890	Per cent of increase.
Total .....	\$9,838,015	\$5,792,733	69.8
Land .....	364,075	367,010	10.8
Buildings .....	1,927,731	1,049,005	33.8
Machinery, tools, and implements .....	1,237,948	1,290,598	14.1
Cash and sundries .....	6,308,261	3,086,170	104.4

<sup>1</sup> Decrease.

From Table 18 it appears that at the census of 1900 the capital amounted to \$9,838,015, an increase of \$4,045,232, or 69.8 per cent for the decade. This amount was distributed as follows: Land, \$364,075; buildings, \$1,927,731; machinery, tools, and implements, \$1,237,948; and cash and sundries, \$6,308,261. Of the four divisions of capital, cash and sundries shows the largest percentage of increase. This includes cash on hand, bills receivable, unsettled ledger accounts, raw materials, stock in process of manufacture, finished products on hand, and other sundries. In 1900 the amount reported for these items was \$6,308,261, and in 1890, \$3,086,170, an increase of \$3,222,091, or 104.4 per cent. As wine requires maturing or aging before it is marketable, and increases in value with each succeeding year, the quantity carried over by manufacturers from season to season is influenced by prices and general market conditions, and may be out of proportion to the quantity annually produced. For this reason the increase or decrease of live capital may, through "finished products on hand," be disproportionate to an advance or decline in the general conditions of the industry.

A slight decrease in the value of land is shown for the decade, but this is due to differences in inventories and estimates. While the capital invested in vineyards is increasing rapidly, the value of land actually utilized in the manufacture of wine may change but little. Wine-making establishments are often difficult of correct classification, because the industry includes both agricultural and manufacturing enterprise. In almost every state considerable quantities of wine are made from small vineyards attached to gardens or farms. Wine, when so manufactured, belongs to the agricultural products of the country, and at the Twelfth Census was returned to the division of agriculture. Such wines are made primarily for home consumption, although small quantities are often retailed in the neighborhood. In contradistinction to this class of producers are the large establishments, not engaged directly or indirectly in grape growing, which manufacture wine

from must and grapes purchased in the open market, or on contract with vineyardists; these are purely manufacturing enterprises. Intermediate between these extremes are those establishments engaged in both grape growing and wine making, the winery being attached to the vineyard, and working into the finished product not only its own crops, but also those of neighboring vineyards. In such cases the two branches of enterprise in which each establishment is engaged have been separated, and there is included in this report only statistics of that branch of the industry relating to manufactures. Statistics pertaining to the growing and harvesting of grapes are included in the reports of the division of agriculture.

A slight decrease is shown in capital invested in machinery, tools, and implements, which decrease is due to the differences incident to inventories and estimates. The growth of the equipment for wine manufacture is better shown by the capital invested in buildings, which increased during the decade from \$1,049,005 to \$1,927,731, or 83.8 per cent. In this item increased cellarage, tanks, and cisterns are included. The equipment for wine making consists for the most part of tanks, cisterns, cooperage, cellarage, machinery for stemming and crushing grapes, and pumps and hose for moving the wine at different stages in the process of maturing. In California machines capable of stemming and crushing 300 tons of grapes daily are in use, and tanks or cisterns with a capacity for 25,000 to 30,000 gallons are common; the largest cistern in the state was constructed by the Italian-Swiss colony, and holds 500,000 gallons.

Table 18 does not include, for 1900, 12 idle establishments, with a capital of \$70,026, and 113 active establishments, each with a product less than \$500, with a capital of \$55,542. The combined capital of these two classes was \$125,568, making an aggregate capital for the industry of \$9,963,583.

Table 19 summarizes, by states and territories, the statistics for the industry as reported at the censuses of 1890 and 1900.

TABLE 19.—LIQUORS, VINOUS: COMPARATIVE SUMMARY, BY STATES AND TERRITORIES, 1890 AND 1900.

<sup>1</sup> No establishments reported.

<sup>2</sup> Included in "all other states" for 1890.

<sup>3</sup> Included in "all other states" for 1900.

<sup>4</sup> Includes establishments distributed as follows: Alabama, 2; Arizona, 1; Florida, 1; Kansas, 2; Mississippi, 2; New Hampshire, 1; New Mexico, 1; Texas, 2; West Virginia, 1; Wisconsin, 2.

<sup>5</sup> Includes establishments distributed as follows: Connecticut, 1; Florida, 2; Illinois, 2; Indiana, 1; Iowa, 2; Michigan, 2; New Hampshire, 1; North Carolina, 2; Oregon, 1; Rhode Island, 1; South Carolina, 1; Texas, 2; Virginia, 2.

At the census of 1900, 15 states reported 344 establishments out of a total of 359 for the United States. In capital and value of products California ranked first, New York second, and Ohio third. In number of establishments these positions were reversed for New York and Ohio. The combined capital of these 3 states was \$8,437,783, out of a total of \$9,838,015 for the United States, and their combined product was valued at \$5,682,103, out of a total value of \$6,547,310. In this group of states New York showed the greatest percentage of increase in number of establishments, capital, and value of products, due to the growth of champagne manufacture in the Keuka Lake district.

Table 20 shows the quantity and cost of materials used and the quantity and value of products for the census year ending May 31, 1900.

TABLE 20.—LIQUORS, VINOUS: MATERIALS AND PRODUCTS, 1900.

	Unit of measure.	Quantity.	Cost of materials.	Value of products.
Materials:

Fuel, and rent of power and heat			79,313	
Mill supplies			9,021	
All other materials			782,254	
Freight			66,326	
Products:				
Total value				\$6,547,310
Still wines	Gallons	23,256,512		5,680,869
Effervescing wines	Gallons	169,055		664,972
Brandy	Proof gallons	114,185		100,651
All other products				98,793
Custom work				2,025

It appears from Table 20 that 23,425,567 gallons of wine were manufactured, of which 23,256,512 were still wines and 169,055 were effervescing wines, or champagnes. The total quantity shown in the table does not include 61,346 gallons reported from 113 small establishments, each with a product less than \$500; 120,630 gallons reported from distilleries which made wine manufacture subsidiary to the distillation of spirits; and 8,217,512 gallons made on farms and reported on the agricultural schedules. The combined output of these three sources of supply was 8,399,488 gallons, which increased the total production of the United States to 31,825,055 gallons. The quantity of wine exported from the United States for the fiscal year ending June 30, 1900, one month later than the census year, was 1,438,421 gallons. The quantity imported for the same period was 4,412,035 gallons, of which 40,436 were exported, leaving 4,371,599 imported for domestic consumption. This was an excess of imports over exports of 2,933,178 gallons, which, added to the total production of the country, gives 34,758,233 gallons as the annual consumption of the United States, or less than one-half gallon per capita. Figures representing annual consumption are, at best, but close approximations. The quantity of domestic wine actually consumed does not correspond exactly with the excess of production over exports, because no fixed law governs the length of time wine is carried for aging or held by manufacturers for better prices; neither does the quantity of foreign wine consumed

within a given year correspond exactly with the importations. Data for closer approximations, however, are impossible to obtain.

Table 20 shows that 376,503,987 pounds, or 188,252 tons, of grapes were used to produce 23,425,567 gallons of wine, or an average of 124.4 gallons to each ton of grapes.

The average value of champagne was \$3.93 per gallon and of still wine 24.4 cents. Contrary to popular supposition, California is not an extensive producer of champagnes. Of the 169,055 gallons of sparkling or effervescing wines reported for the United States at the census of 1900, 8,880 were returned from California, 15,600 from Ohio, 29,400 from Missouri, and 113,435 from New York.

In Ohio the quantity of wine produced from each ton of grapes was 154.8 gallons; in New York it was 151.5; and in California 118.8 gallons. These differences are due to the varying character of the seasons and to the different varieties of grapes grown for different classes of wine. Different kinds of grapes vary from 60 to 80 per cent in the yield of must. The average cost of grapes per ton in California, New York, and Ohio was \$13.49, \$18.94, and \$19.71, respectively.

The production of brandy by wineries was reported as 114,185 gallons, of which 60,785 gallons were from California. This, however, is only a small fraction of the entire brandy product of the state, which approximated 3,000,000 gallons, of which more than 2,000,000 gallons were used for fortification of wine, and not separately reported. Brandy is a natural by-product of wine manufacture, being distilled from cheese, wash, or piquette. The quantity reported was so manufactured, or was distilled from wine, and does not change the figures in Table 20, from which the above averages were computed. Fifteen gallons of cheese, 10 to 12½ gallons of wash, or 7 gallons of piquette will produce 1 gallon of brandy. Certain grades of wine are sometimes distilled into brandy when the relative activity of the market in the two commodities makes it advantageous to do so; 5 gallons of sweet or 7 gallons of sour wine will, in distillation, produce 1 gallon of brandy. The internal-revenue tax of \$1.10, which is collected on each proof gallon of distilled spirits, does not apply to brandy used in the fortification of wines, or to that deposited in bonded warehouses until it is withdrawn therefrom. According to the report of the Commissioner of Internal Revenue for the fiscal year ending June 30, 1900, 2,137,067 gallons of grape brandy were used in the fortification of angelica, port, sherry, Tokay, muscatel, and other varieties of sweet wines. This quantity was added to 7,544,342 gallons of wine, producing 8,815,441 gallons after fortification.

The wine product of the United States is small com-

pared with that of other wine-producing countries. The estimated crop of the world, by countries, for the year 1901, was as follows:<sup>1</sup>

	Gallons.
France .....	1,530,223,200
Italy .....	1,013,760,000
Spain .....	520,080,000
Portugal .....	155,760,000
Algeria .....	146,440,800
Austria .....	116,160,000
Roumania .....	87,120,000
Chile .....	87,120,000
Russia .....	76,560,000
Bulgaria .....	73,920,000
Germany .....	60,720,000
Argentine Republic .....	55,440,000
Turkey and Cyprus .....	50,160,000
United States .....	39,600,000
Peru .....	36,960,000
Switzerland .....	31,680,000
Servia .....	23,760,000
Brazil .....	12,672,000
Australia .....	8,816,000
Madeira .....	7,920,000
Tunis .....	4,488,000
Cape Country .....	3,168,000
Uruguay .....	2,376,000
Mexico .....	924,000
Persia .....	765,600
Bolivia .....	660,000

According to this estimate, the United States ranked fourteenth in production, and the world's supply for 1901 was 4,146,753,600 gallons, or about 2.8 gallons per capita. In the opinion of United States Consul Covert, of Lyon, France, a general crisis for wine producers is impending, because of an overproduction in the entire world.<sup>2</sup>

Table 21 shows the quantity, value, and destination of wine exported from the United States for the fiscal year ending June 30, 1900.

This table shows that the exports were 1,438,421 gallons, with a value of \$625,592. The United Kingdom purchased the greatest quantity, followed by Hawaii, Mexico, and Germany in the order named.

## HISTORICAL AND DESCRIPTIVE.

Wine was manufactured before the dawn of history. The explanation of this is simple. It is the product of natural forces requiring neither mechanical powers nor manufacturing appliances. In the laboratory of earth and air, sugar is developed in the grape and in turn converted into alcohol. The vine and its fruit are as ancient and as widely distributed as the virgin forests of the earth. The accidental crushing of the grape and collecting of small quantities of its juice were followed by the discovery of its transformation and intoxicating properties after exposure to the air. Systematic observation followed close on accidental discovery, until chance gave way to design, and primitive wine making was ushered in.

The domestication of the vine and scientific methods of wine manufacture came many centuries later, and were among the first achievements of ancient husbandry. The time and labor required to plant and mature vineyards make them too valuable to be abandoned when once established. The cultivation of the vine was, therefore, incompatible with the pursuits of nomadic or seminomadic peoples, and the grape, like the olive, was, among the ancients, the symbol of settled and cultured life. The vine is especially susceptible to modification through culture or deterioration by transplantation, and while it is certain that the ancients cultivated many varieties, it is not possible to identify any of them with a modern botanical classifi-

cation. The wines of Greece and Rome were highly flavored with spices and aromatic herbs, and in those countries viniculture attained its highest development in the vicinity of the Surrentine Hills and on the islands of the Ionian and Ægean seas. A detailed description of ancient methods of manufacture and the progress of viniculture westward with the movements of civilization to its installation and development in the modern wine provinces of Europe does not, however, fall within the scope of this report.

In that portion of the New World now within the boundaries of the United States, the native vines were distributed from ocean to ocean and from Michigan to Florida. Pre-Columbian adventurers from the North, driven by gales to the shores of the Atlantic, gave the name of Vinland to a portion of the coast; and all the American explorers after Columbus, at whatever point they touched the shore, or however far they penetrated the interior, found grapes in profusion and variety. The American colonists all came from countries in Europe where the manufacture of wine had for centuries been an important industry. It is true that viniculture in England had declined owing to the importation of French wines after the Norman Conquest, but the English colonists were none the less familiar with the beverage and its uses. It is but natural, therefore, that the attention of the different colonies should have been early attracted to the cultivation of the native

grape and its manufacture into wine as a possible source of revenue in the new country. Their hopes and expectations were greatly accentuated by the early writers, who gave florid descriptions of the abundance and luxuriance of the vines. In consequence, the efforts to introduce the culture of the grape for wine manufacture, made during our colonial period, were numerous, and common to all the settlements. Almost without exception, however, they were expensive and discouraging. In the more northern colonies the attempts were not long persevered in. This is particularly true of the colonies of New England. Massachusetts and her neighboring settlements had wild grapes, perhaps in as great abundance as Virginia, but interest in viniculture languished as the colony increased its exports of fish, lumber, and bread-stuffs to the West Indies, Spain, Portugal, and the Wine Islands, receiving from those countries wines in reciprocal trade. In common with all the other colonies those of the South failed in their efforts to introduce European varieties of grapes and failed also in attempts to domesticate the native vine. The work of caring for vineyards, particularly the dressing of vines in a way to secure best results, requires workmen of a high order of intelligence, the exercise of which was incompatible with the system of slavery under which the vigneron were at first compelled to toil.

After the failure to acclimate European vines it is not strange that colonial wine manufacture proved unprofitable, because the product of the native grape could not, as an article of export, compete with the products of other countries, perfected by the accumulated experience of centuries of wine making; and domestic consumption in a new country is always insufficient to create a profitable demand. Wine making is profitable only in an advanced state of society with accumulated riches for the gratification of luxurious tastes.

The first wine manufactured in the United States was made from the native wild grapes by the Spanish colonists in Florida, about 1565. An attempt at grape culture was made in Virginia in 1610, three years after the settlement of Jamestown, by Frenchmen who came to the colony to plant a vineyard. Later, about 1620, the London Company sent French vineyardists to the colony for the same purpose. As far west as Kaskaskia, Ill., the French colonists in 1769 made wine from the wild grapes. In 1802 Congress made grants on the Ohio River in Indiana to John J. Dufour, a native of Switzerland, who had been experimenting with foreign varieties of grapes near Lexington, Ky., and who represented a colony of Swiss emigrants, including several members of his own family. The colony settled at New Switzerland (now Vevay, Ind.) to engage in the planting of vineyards and the making of wine. These emigrants carried on the culture of the grape in a small way for a number of years, attaining moderate success with the Madeira and other foreign varieties, but a

greater measure of success with the Schuylkill, an offspring of the native fox grape. In 1810 the settlement had 8 acres in vineyards and made 2,400 gallons of wine, valued at \$6,000. In 1818, 5,000 gallons were made which sold at \$1 a gallon, but the fact that this product was from small vineyards attached to separate farms would seem to indicate that the industry was being neglected for other lines of agriculture.

The first statistical reports of the United States Government on wine manufacture are contained in the abstract of the census of 1810, compiled by Tench Coxe, and published at Philadelphia in 1814. From this abstract it appears that there were reported at the Third Census 14,191 distilleries, producing 22,977,167 gallons of spirits from fruit and grain and 2,827,625 gallons from molasses; 132 breweries making 182,690 barrels, or 5,754,735 gallons, of malt liquors; and wineries (number not mentioned) producing 11,755 gallons of wine, of which 9,230 gallons were made from currants and 2,525 from grapes. Of the total quantity of wine reported, 4,875 gallons were from Rhode Island, 4,480 from Pennsylvania, and 2,400 from Indiana. The Moravians had long carried on the manufacture of currant wine at Bethlehem, Pa., and Mr. Coxe in his report strongly urged its manufacture as being more profitable than that of grape wine. The total quantity of wine reported at the Third Census seems a small product after two hundred years of effort. It probably fell short of the real production, because it could not have included limited quantities made for home consumption from small and widely scattered vineyards attached to farms.

The first really successful attempt at wine making, and the one which might be regarded as the first of commercial importance, was made by Nicholas Longworth at Cincinnati, Ohio. He experimented first with vines procured from the Swiss settlement at Vevay, Ind., but later abandoned these for the Catawba, which he procured from John Adlum, of Georgetown, D. C. This particular variety of grape has played an important part in the development of the wine industry of the United States. In 1820 Mr. Adlum called the attention of Congress to the fact that he had succeeded in making a superior quality of wine from the Catawba grape, and asked the use of certain public lands in the District of Columbia for an experimental vineyard. His request was refused. Previously, in 1819, he had discovered a vine of the Catawba growing in the garden of an inn at Clarksburg, Md., and secured cuttings, which he planted in his vineyard on Rock Creek; and it was from him that Mr. Longworth, in 1825, secured cuttings for his vineyards at Cincinnati. This grape, when found by Mr. Adlum, was supposed to be a European variety, but is now thought to be a pure native. It was traced back to the Catawba River in North Carolina, from which it takes its name.

After the decline of the industry at Cincinnati, the

cultivation of the Catawba was continued on the islands near the southern shore of Lake Erie. It is still cultivated there, and on the mainland in the vicinity of Sandusky, with considerable success. The greatest Catawba region at the present day, however, is the Keuka Lake district in central New York, where the grapes ripen on the hillsides sloping down to the lake. In both the Ohio and New York districts this variety is largely used for the manufacture of American champagne. Mr. Longworth spent about forty years in trying to make American wine manufacture a success on the banks of the Ohio River, and at one time, about 1860, it was estimated that there were 2,000 acres in vineyards in the vicinity of Cincinnati. The decline of the industry in the Cincinnati district was due to the destruction of the vineyards by the black rot and the susceptibility to that disease of the varieties of grapes there cultivated.

Since the beginning of commercial wine manufacture, the states of New York and Ohio have maintained supremacy over the other states east of the Rocky Mountains, except at the census of 1870, when the product of Missouri exceeded the combined product of both those states, and at the census of 1890 exceeded that of New York. At the census of 1860 the total value of the product for the United States was \$400,791; for New York, \$155,966; and for Ohio, \$47,275. At the census of 1870 the value for the United States was \$2,225,238; for Missouri, \$934,442; for New York, \$296,668; and for Ohio, \$309,375. At the census of 1880 the value for the United States was \$2,169,193; for Missouri, \$185,900; for New York, \$375,150; and for Ohio, \$773,110. At the census of 1890 the value for the United States was \$2,846,148; for Missouri, \$244,300; for New York, \$156,740; and for Ohio, \$550,777. At the census of 1900 the value for the United States was \$6,547,310; for Missouri, \$199,130; for New York, \$942,548; and for Ohio, \$801,634.

East of the Rocky Mountains the transplantation of European varieties of grapes for wine manufacture has not, to the present day, been attended with any measure of success. The Lake Erie district in Ohio, the lake districts of central New York, and the Hudson River Valley are the only producing sections of real importance, and here the rigors of the climate are inimical to the success of foreign varieties. All the wine manufactured in these districts is from pure natives or from natural and artificial hybrids.

In the state of California wine manufacture has had a rapid growth. There, contrary to the universal experience east of the Rocky Mountains, efforts to supplant indigenous vines by the acclimation of foreign varieties have been attended with a marked degree of success. Of the 23,425,567 gallons of wine reported at the census of 1900, 19,028,258 gallons were made in California. This is more than four times the combined output of all the other states, and practically all was made from European varieties which have adapted themselves to

their new environment. The introduction of the foreign vine into California dates back to 1771. It was brought from Spain by way of Mexico through the instrumentality of the Catholic missions. The mission of San Gabriel planted the first vineyard, and the planting of vines extended from mission to mission until vineyards comprising from 5 to 30 acres stretched from San Diego to Sonoma. The labor was performed by the native Indians, whom the Spaniards reduced to slavery and taught the elementary lessons of grape culture. The variety cultivated was what is now known as the Mission grape. It proved to be of lasting favor with the Spanish fathers, because its wine resembled somewhat the red wines of old Castile. All the missions grew this one variety, but with the characteristic susceptibility of the vine to soil and climatic conditions the fruit took on various modifications in size, appearance, and flavor in the different localities where cultivated. For this reason, and because of different methods of treating the expressed juices, there was much variation in the general character and fineness of the wine. The Mission grape produced from 700 to 1,000 gallons of wine to the acre, and practically all was consumed in the neighborhood. There were no facilities for export; neither were there casks or bottles. For these reasons the industry can hardly be said to have reached the dignity of commercial importance, and its products were seldom seen in the marts of trade. The wine was fermented in cemented cisterns, where it was allowed to remain, or was drawn into hides or earthenware jars.

With the downfall of the Spanish power in Mexico the California missions waned, and with them viticulture declined also. In 1845 the missions were abolished and confiscated, and the Americans, when they came into possession, found both missions and vineyards in ruins. The concentrated interest of the people in the mining of gold, following its discovery in 1849, resulted in the neglect of agricultural pursuits, and grape growing and wine making remained undeveloped.

In 1856 statistics for the state showed approximately 1,500,000 vines, of which the Spanish settlement at Los Angeles had about 750,000. The others were scattered among the missions and Spanish ranches and were nurtured by irrigation. A. Haraszthy was the first to demonstrate the possibility of maturing grapes without irrigation by a system of stirring the soil around the roots of the vine. In 1858 he wrote an essay on vine planting and wine making which, with other literature on the subject, was given wide circulation by the State Agricultural Society. This so stimulated interest in viniculture that by 1862 the standing committee of the legislature reported 20,000,000 vines planted throughout the state.<sup>1</sup>

In 1861 a joint resolution of the legislature of Cali-

<sup>1</sup> Harper's Magazine, 1864, vol. 29, page 24.

fornia authorized and requested Governor Downey to appoint a commission to report "upon the ways and means best adapted to promote the improvement and growth of the grapevine in California."<sup>1</sup> Mr. Haraszthy, as a representative of this commission, visited the famous wine districts of Europe and purchased 100,000 vines, embracing about 1,400 different varieties, which were propagated at Sonoma. Cuttings from these vines were distributed among growers in different parts of the state. From that time the manufacture of wine in California has had a continuous and marvelous growth, interrupted only by the depreciation of prices through overproduction in certain years. In prolific seasons must have sold as low as 7 or 8 cents a gallon, which hardly equaled the cost of production. In 1860 the value of the product was \$160,300; in 1870, \$602,553, in 1880, \$622,087; in 1890, \$1,738,863; and in 1900, \$3,937,871.

Since the introduction of European vines the product of California has included duplications, more or less perfect, of most of the well-known varieties of European wines. California embraces nearly ten degrees of latitude. With the ocean on the west and the altitudes rising into the mountains on the east, with the hills, valleys, rivers, and slopes, the state has such a variety of soil, slope, elevation, temperature, and climatic conditions as to reproduce, somewhere within its borders, any wine now manufactured. At present, however, the dry wines have the characteristic heaviness common to the wines of all southern countries, where warmth and sunshine develop a large proportion of sugar in the grape, which in fermentation is transformed into an excess of alcohol. In time, however, through the discovery of new districts, the evolution of new varieties of grapes, the accumulated experience of vineyardists and wine makers, and the adaptability of consumers to the article consumed, California will resolve itself into wine districts, the products of which will be prized as those of the famous wine provinces of Europe.

#### CLASSIFICATION AND NOMENCLATURE.

According to the quantity of sugar retained by the arrest of fermentation, wines are divided into sweet and dry; according to color, into red and white; and according to the quantity of carbonic acid gas generated in fermentation and retained under pressure, into still and effervescing wines (champagnes). The quantity of sugar contained in grapes used for wine making is influenced by many conditions, such as the variety of the grape, soil, climate, and the vicissitudes of the seasons, and will vary from 13 to 30 per cent. In fermentation sugar is converted into alcohol, and for the sweet wines the grapes rich in sugar content are chosen; before enough of the sugar is fermented out to convert the juice into a dry wine, some form of alcohol, preferably grape brandy, is added to give the requisite alcoholic strength and to arrest fermentation.

Alcohol, by preventing further fermentation, fortifies against deterioration; hence the name "fortified," applied to all classes of sweet wines. Such wines invite adulteration or a deviation from natural processes of manufacture. Sugar, alcohol, and water may be added to the juice to the point of sacrificing its characteristic flavor, which would insure detection. In all wines there is considerable sugar remaining after the first violent fermentation, and by natural process this ferments out slowly through a considerable period of time. The extent to which it is fermented out determines the degree of dryness, as wines shade easily into either classification. Usually, however, grapes lighter in sugar content are chosen for dry wines, because the desired dryness can be secured by the fermentation of less sugar, leaving the wine of less alcoholic strength.

Red wines are made from grapes with highly colored skins, which are fermented with the juice, and from which the alcohol, formed by the fermentation of the sugar, absorbs the coloring matter. The alcohol also takes up certain acids and other ingredients from skins and stems, which give the red wines a distinct physiological effect, principally through the astringent properties of tannin. White wines are usually made from distinct types of light-colored grapes fermented without the skins.

Champagne is an effervescing wine, named from the province in France where it was first manufactured. Distinct types of grapes, as well as districts that will produce them, are necessary for its perfect production. The effervescence is due to carbonic acid gas generated in fermentation and retained under pressure. After the juice has passed through certain stages of fermentation it is bottled in heavy glass and tightly corked, the cork being bound in by wire passed over the mouth and around the neck of the bottle. Fermentation continues and the gas generated is confined, producing a natural "charging" which, on the opening of the bottle, gives to the wine its effervescence. The manufacture of champagne entails great labor, time, and skill. About three years are necessary to perfect it, and all this time it requires constant care and handling; at different stages of the process it must be uncorked to expel sediment. There are all grades of champagne sold in the markets, from an inferior grade of wine artificially "charged," to the wine of the highest type of grapes, perfected by natural processes.

Sweet and dry wines shade off into several types, rather than distinct classifications, and may be red or white, still or sparkling. These types take their names from provinces or from cities and towns in wine districts. Under these types are numerous brands named after valleys, villages, provinces, estates or chateaux, or after some fanciful name of the producer. A modern first-class hotel usually lists its wines under the headings of champagnes, clarets, Sauternes, Rhine wines, Burgundies, sherries, Madeiras, and ports. Champagnes are subdivided into foreign and domestic, and are classed as sweet, dry, and extra dry. Claret is a name given to dry reds or those of a general Bordeaux

<sup>1</sup>Appendix to Journals of Senate and Assembly, California, thirteenth session, 1862.

type; Sauternes, from a city near Bordeaux, are dry whites; Rhine wines are those from the wine districts of Germany along the Rhine River and are dry wines, usually white, but sometimes red; Burgundies, named from Burgundy, are dry wines, red or white, still or sparkling; sherries, from Xeres, Spain, are fortified wines, but, as some are much sweeter than others, they are designated as sweet or dry sherries, and are white or

tinted still wines; Madeiras, after the island of Madeira, are much like sherries; ports, from Oporto, Portugal, are still wines, sweet, and usually red. Among the sweet wines, California manufactures large quantities of ports and sherries, and among the dry wines, clarets and Sauternes.

Table 22 gives detailed statistics of the wine industry, by states and territories, as reported at the census of 1900.

(637)

# TOBACCO.

By JOHN H. GARBER.

For the census of 1900, manufactures of tobacco were divided into three groups or classes, namely: Cigars and cigarettes; chewing and smoking tobacco and snuff; and tobacco, stemmed and rehandled. Statistical inquiries were grouped correspondingly, and the principal statistics for each classification and the combined totals are presented in Table 1.

TABLE 1.—MANUFACTURES OF TOBACCO: SUMMARY FOR 1900.

	Total.	Cigars and cigarettes.	Chewing and smoking tobacco and snuff.	Tobacco stemming and rehandling.

Miscellaneous expenses.....	\$79,495,422	\$31,436,701	\$47,583,705	\$525,016
Cost of materials used.....	\$107,182,656	\$57,946,020	\$35,038,287	\$14,198,349
Value of products.....	\$283,076,546	\$160,223,152	\$103,754,362	\$19,099,032

The value of cigars and cigarettes was 56.6 per cent of the total value of all tobacco manufactures; chewing and smoking tobacco and snuff, 36.7 per cent; and tobacco, stemmed and rehandled, 6.7 per cent. The manufacturers of cigars and cigarettes, and of chewing and smoking tobacco and snuff, use a considerable quantity of material as it comes from establishments engaged in the business of stemming and rehandling, and there is, therefore, for the three classes of tobacco factories, a duplication of values such as is common to correlative industries some of which use material in partially manufactured form.

Through the excise system of the General Government the Bureau of Internal Revenue comes into possession of statistics of materials used in tobacco manufac-

ture, and also of the quantity of the different classes of finished products. This information is given to the public in the form of annual reports by the Commissioner of Internal Revenue, which reports, however, do not include statistics of capital, wage-earners, wages, cost of materials, miscellaneous expenses, or value of products. The tabulations of the Census Office for this manufacture are designed to present information supplementary to that published by the Bureau of Internal Revenue, duplicating only the number of establishments. In this item, however, the reports of the two bureaus can not be expected to agree because of the elimination of very small establishments by the Census Office from its canvass and the difference in methods of classification.

Table 2 shows the quantity of leaf tobacco used in the three principal groups of its manufactures, for each fiscal year from 1890 to 1900, inclusive. This table is taken from the reports of the Commissioner of Internal Revenue, 1900 and 1901.

TABLE 2.—LEAF TOBACCO: QUANTITY USED IN MANUFACTURES, 1890 TO 1900, INCLUSIVE.

[From reports of Internal Revenue Commissioner 1900 and 1901.]

YEAR.	NUMBER OF POUNDS OF LEAF TOBACCO USED.

The total production of the United States for 1900 was 868,163,275 pounds, an increase of 379,906,629 pounds, or 77.8 per cent, over the crop of 1890. All the states and territories were represented except Colorado, District of Columbia, Nevada, Rhode Island, and Utah, but the cultivation of tobacco on a large scale was confined to comparatively few states. The crop of only 18 states exceeded 1,000,000 pounds each, and that of 13 states, 5,000,000 pounds each. Eight states produced more than 20,000,000, and 3 states more than 100,000,000 pounds each. Kentucky, North Carolina, Virginia, Ohio, and Tennessee, in the order named, were the greatest 5 producers, whose combined crop was 679,791,000 pounds, or 78.3 per cent of the entire production. Kentucky alone produced 36.2 per cent of the entire crop of the United States. The genesis of American tobacco culture was in Virginia, and that state exceeded any other in quantity grown until 1870, when Kentucky took first place. Among the leading producers, North Carolina showed the greatest percent-

age of increase for the decade between the Eleventh and Twelfth censuses, and in 1900 ranked second in quantity grown, Virginia being third. The 868,163,275 pounds shown in Table 3 as the total production of the United States was valued at \$56,993,003, or an average of 6.6 cents a pound. This was grown from 1,101,483 acres of land, distributed among 308,317 farms, the average crop being 788.2 pounds per acre. It is estimated upon the experience of a series of years that the United States grows approximately one-half of the world's supply of tobacco.

During the fiscal year ending June 30, 1900, the United States exported 344,655,697 pounds of unmanufactured tobacco, consisting of leaf, stems, and trimmings. Table 4, compiled from "Commerce and Navigation of the United States, Bureau of Statistics, Treasury Department," shows by countries the imports and foreign and domestic exports of tobacco and its manufactures for the fiscal year 1900.

<sup>1</sup> Commerce and Navigation of the United States. United States Treasury Department, 1900.

Of the total quantity exported, the United Kingdom took 121,959,070 pounds, valued at \$10,961,716. Germany, France, Italy, and the Netherlands, in the order named, were the next heaviest purchasers. Belgium and Spain were also important buyers of American tobacco, taking 17,146,300 and 13,772,478 pounds, respectively. Of the foreign countries in the Western Hemisphere, Canada and Mexico received the largest shipments, the former purchasing 10,303,395, and the latter 2,686,758 pounds. Of the 3,583,978 pounds exported to Asia, Japan received 3,104,472, or 86.6 per cent. Of the 3,766,835 pounds shipped to Oceania, British Australasia took all but 928. A total of 4,059,304 pounds were exported to Africa; of this amount British Africa received 2,630,760 pounds, or 64.8 per cent.

Table 4 is an accurate presentation of the quantity and value of the consignments of unmanufactured tobacco exported to the various countries of the world, but is not altogether reliable as an index to its final distribution and place of consumption. It is thought that practically all the tobacco exported to the United Kingdom is consumed within British possessions, but much of that exported to Germany is distributed from Bremen and other German ports to Austria-Hungary, Switzerland, Africa, and several other countries. The Regie system prevails in Italy, France, Spain, and Japan, and the quantity of American tobacco exported to those countries might be said to correspond exactly with its consumption. The quantity of pure leaf exported to the United Kingdom was 89,618,817 pounds in 1895; 79,063,780 pounds in 1896; 89,664,950 pounds in 1897; 88,366,290 pounds in 1898; and 85,395,232 pounds in 1899. The quantity exported to Germany was 51,311,070

pounds in 1895; 53,693,132 pounds in 1896; 64,304,001 pounds in 1897; 53,787,518 pounds in 1898; and 44,216,962 pounds in 1899. The quantity exported to France was 34,943,161 pounds in 1895; 33,792,243 pounds in 1896; 23,762,881 pounds in 1897; 22,016,203 pounds in 1898; and 23,656,171 pounds in 1899. The quantity exported to Italy was 24,542,652 pounds in 1895; 32,218,201 pounds in 1896; 27,472,628 pounds in 1897; 23,432,941 pounds in 1898; and 27,397,587 pounds in 1899. The quantity exported to the Netherlands was 17,765,213 pounds in 1895; 19,148,254 pounds in 1896; 26,489,855 pounds in 1897; 18,282,505 pounds in 1898; and 21,170,683 pounds in 1899.

In 1900, the imports of unmanufactured tobacco amounted to 19,619,627 pounds, valued at \$13,297,223. Of the total quantity imported, 5,561,068 pounds were for cigar wrappers, of which 5,048,194 pounds, or 90.8 per cent, were grown by Dutch syndicates in the island of Sumatra and imported from the Netherlands. Of the 14,058,559 pounds imported, not suitable for cigar wrappers, 11,272,334 pounds, or 80.2 per cent, came from Cuba.

At the census of 1880 all phases of the tobacco industry, including both its cultivation and manufacture, received comprehensive treatment. The report of the industry at that census embraced statistics showing collectively the imports and the foreign and domestic exports of both manufactured and unmanufactured tobacco for the United States for each fiscal year from 1791 to 1880, inclusive. Table 5 of this report is intended to be supplementary to the import and export table of 1880, and shows the same items for each fiscal year from 1881 to 1900, inclusive.

Men, 16 years and over	62,168	59,452	40,999	21,409	7,266	4.6	48.3	87.3	194.6
Wages	\$29,963,405	\$28,866,765	(2)	(2)	(2)	8.8			
Women, 16 years and over	37,762	24,214	9,108	2,615	731	56.0	165.9	248.3	257.7
Wages	\$10,505,052	\$7,174,765	(2)	(2)	(2)	46.4			
Children, under 16 years	3,532	3,334	4,090	2,025	(2)	5.9	118.5	102.0	
Wages	\$457,139	\$433,530	(2)	(2)	(2)	5.4			
Miscellaneous expenses	\$31,436,701	\$17,673,063	(4)	(4)	(4)	77.9			
Cost of materials used	\$57,946,020	\$50,298,980	\$29,577,833	\$13,047,370	\$3,511,312	15.2	70.1	126.7	271.6
Value of products	\$160,223,152	\$129,693,275	\$63,979,575	\$33,373,685	\$9,068,778	23.5	102.7	91.7	268.0

<sup>1</sup>Includes proprietors and firm members with their salaries; number only reported in 1900, but not included in this table. (See Table 11.) <sup>2</sup>Decrease. <sup>3</sup>Not reported separately. <sup>4</sup>Not reported.

Table 6 shows, for the four decades, a rapid growth in number of establishments, capital, wage-earners, wages, and value of products. The \$13,763,638 increase in miscellaneous expenses from 1890 to 1900 is not disproportionate to the general expansion of the industry, as might appear, because the item includes internal-revenue tax, which was increased within the decade. The value of products shown by the table represents their value at the factory, packed or cased in marketable form ready for shipment, with the necessary revenue stamps affixed. The revenue tax is, therefore, a factor in the determination of such values, and its variation with different legislative acts should be considered in making comparisons. In the period covered by this report the tax was \$3.60 a thousand on cigars and cigarettes weighing more than 3 pounds to the

thousand; on cigars and cigarettes weighing not more than 3 pounds to the thousand the tax was \$1 and \$1.50 a thousand, respectively.

From Table 6 it appears that for the decade ending with 1900 there was an increase in all items except in number of salaried officials, superintendents, managers, clerks, and salesmen, and their salaries. These exceptions are chiefly due to differences in methods of classification at the censuses of 1890 and 1900 as explained in the letter of transmittal accompanying this report. The present tendency of manufacturing to centralize into single corporations has also resulted in lessening the number of persons employed in supervision and management.

Table 7 is a comparative summary of cigars and cigarettes, by states and territories, 1890 and 1900.

The manufacture of cigars was widely distributed in 1900, every state except Mississippi being represented in the census returns for that year. Table 7 shows an increase in value of products from 1890 to 1900 for every state reporting three or more establishments except California, District of Columbia, Louisiana, Maryland, North Carolina, North Dakota, South Carolina, and Vermont. The cause for a decline in this industry in individual states, simultaneous with a substantial increase for the entire country, is not easy to explain. In addition to the vicissitudes common to local or neighborhood manufacturing, it is often due to the establishment of an improved factory system in the field of trade formerly occupied by the industry of a particular state, and in consequence, to the encroachments of competition; or it may be due to the policy of large corporations in withdrawing the manufacture of a particular form of product from one state to locate it in another whose position is more advantageous for lessening cost of production or securing control of markets. For example, a large factory producing both cigars and paper cigarettes may be absorbed by a corporation which withdraws from it the manufacture of cigars to other points, and continues in it only the manufacture of cigarettes. The products of one state are thus decreased while those of other states are increased correspondingly.

New York, Pennsylvania, Ohio, Florida, and Illinois, in the order named, were the leading 5 states in value of cigar and cigarette products in 1900. No cigarettes, however, were made in Ohio, and the value of products shown by the table for that state represents cigars exclusively. Only limited quantities of cigarettes were manufactured in Pennsylvania, Florida, and Illinois,

but New York produced more than any other state. The combined cigar and cigarette manufactures of the greatest 5 producing states enumerated above were valued at \$111,384,213, or 69.5 per cent of the total for the United States.

Of the capital invested in this branch of the industry, 5.8 per cent was in land, 9.2 per cent in buildings, 5.4 per cent in machinery, tools, and implements, and 79.6 per cent in cash and sundries. Of the miscellaneous expenses, 6.3 per cent was for rent of works, nine-tenths of 1 per cent for taxes, not including internal revenue, 92.7 per cent for rent of offices, insurance, interest, internal-revenue tax, repairs, advertising, and other sundries, and one-tenth of 1 per cent for contract work.

Table 8 shows the cost of materials used in the manufacture of cigars and cigarettes, 1900, with the per cent each class is of the total.

TABLE 8.—CIGARS AND CIGARETTES: COST OF MATERIALS, 1900.

	1900	
	Amount.	Per cent of total.
United States.....	\$57,946,020	100.0
Purchased in raw state.....	49,250,057	85.0
Purchased in partially manufactured form <sup>1</sup> .....	7,923,140	13.7
Fuel.....	278,067	0.5
Rent of power and heat.....	37,986	0.1
Freight.....	416,170	0.7

<sup>1</sup> Includes "all other materials" and "mill supplies;" the latter is shown separately in Table 11.

Table 9 shows, by states and territories, the quantity of materials used and the number of each kind of cigars and cigarettes manufactured for the calendar year 1900.

TABLE 9.—CIGARS AND CIGARETTES: MATERIALS AND PRODUCTS, BY STATES AND TERRITORIES, CALENDAR YEAR 1900.

This table shows that the combined production of cigars and cigarettes for the year ending December 31, 1900, approximated nine and one-half thousand millions. More than one hundred and eighteen million pounds of tobacco were used in their manufacture, the average being 12.6 pounds of tobacco to each thousand cigars and cigarettes. In cigars alone, an average of 17.1 pounds of tobacco were used to each thousand, and in cigarettes an average of 4 pounds. Pennsylvania was the leading state in the separate manufacture of cigars, with a production of 1,624,527,885; New York, Ohio, Maryland, and Illinois followed in the order named, with 1,291,273,550; 658,819,883; 403,548,626; and 281,400,268, respectively. The combined product of these 5 states was 4,259,570,212, or 69 per cent of the entire output of the United States.

The records of the Bureau of Internal Revenue show that, for the year ending December 31, 1900, the leading 10 cities in cigar manufacture, in the order of their production, were New York, N. Y.; Cincinnati, Ohio; Philadelphia, Pa.; Pittsburg, Pa.; Richmond, Va.; Chicago, Ill.; Baltimore, Md.; Lancaster, Pa.; Tampa, Fla.; and Detroit, Mich. The output of the extremes

(New York and Detroit) approximated 760,000,000 and 100,000,000 cigars, respectively.

The geographical distribution of cigarette manufacture is much more limited than the manufacture of cigars. Only 19 states are represented in Table 9, and the output of a majority of these was comparatively small. New York led, with an output of 1,746,454,120, followed by Virginia, North Carolina, Louisiana, and California, in the order named, with 742,933,030; 649,314,810; 48,249,800, and 31,522,880 cigarettes, respectively. The combined production of these 5 states was 3,218,474,640, or 98.8 per cent of the entire product of the United States.

The leading 10 cities in cigarette production for the calendar year, 1900, were New York, N. Y.; Richmond, Va.; Durham, N. C.; Rochester, N. Y.; New Orleans, La.; Lynchburg, Va.; San Francisco, Cal.; Wilson, N. C.; Chicago, Ill.; and Philadelphia, Pa. The production of the extremes (Greater New York and Philadelphia) approximated 1,370,000,000 and 9,000,000 cigarettes, respectively.

Table 10 shows the number of cigars and cigarettes withdrawn from factories for shipment and tax-paid, for each fiscal year from 1863 to 1900, inclusive.

TABLE 10.—CIGARS AND CIGARETTES: NUMBER WITHDRAWN FOR CONSUMPTION AND TAX-PAID, FOR EACH FISCAL YEAR FROM 1863 TO 1900, INCLUSIVE.

[Compiled from report of Commissioner of Internal Revenue, 1900.]

FISCAL YEAR ENDED JUNE 30—	Aggregate number.	Cigars.	Cigarettes.

<sup>1</sup> From September 1, 1862.

<sup>2</sup> Including cigarettes not separately reported.

Tables 9 and 10 cover different years, neither of which agrees with the census year ending May 31, 1900. The correspondence is sufficiently close for approximations, but for absolute accuracy the differences should be considered. The number of cigars and cigarettes on which taxes were paid during the fiscal year ending June 30, 1900, shown by Table 10, falls considerably short of the number manufactured during

the calendar year 1900, shown by Table 9. The discrepancy is explained by the difference in period of time covered by the two tables, and by the lack of correspondence between the number actually made and that withdrawn for consumption. Internal-revenue tax is not collected on cigars and cigarettes withdrawn for export, nor on those intended for domestic consumption, until withdrawn from the warehouses of the manufacturers. Products exported and those remaining in factory warehouses do not, therefore, appear in Table 10, but importations are included. The number of cigars and cigarettes tax-paid is doubtless a better index to consumption than is the number manufactured, but the annual average withdrawn for a period of years should be considered in computing annual consumption, because a marked increase or decrease in the number tax-paid from one year to another may be due to the policy of establishments in forcing manufactures and deliveries pending an increase in internal-revenue tax, or withholding them pending a reduction. The decrease in number of cigarettes since 1897, as shown by Table 10, is in part due to such policy and in part to the increasing consumption of cigarettes manufactured by the consumer from prepared tobacco put upon the market in packages accompanied by cigarette wrappers, which are given to the consumer in separate form. Cigarettes when so manufactured do not, of course, appear in statistical reports.

Table 4 shows, by countries, the imports of cigars, cigarettes, and cheroots, and the foreign exports of the same articles, for the fiscal year ending June 30, 1900, expressed in pounds and value. The number and value of domestic exports of cigars and cigarettes is also given by countries in this table, and Table 5 shows the same items for each fiscal year from 1880 to 1900, inclusive.

Table 11 is a detailed summary for cigar and cigarette manufacture, by states and territories, for the census year ending May 31, 1900.

<sup>1</sup> Classified as tobacco and snuff.  
<sup>2</sup> Decrease.

<sup>3</sup> Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 17.)

<sup>4</sup> Not reported separately.  
<sup>5</sup> Not reported.

In the manufacture of chewing and smoking tobacco and snuff, capital increased \$34,362,165, or 361.9 per cent, and value of products \$81,933,827, or 375.5 per cent in the forty-year period ending with 1900. The rise and fall in number of establishments shown by Table 12 is due to differences in the thoroughness of the canvass of small factories at different censuses, and also to different methods of grouping and classifying establishments by character of products. This item is influenced, too, by the concentration of the industry into large corporations and by the special taxes levied by internal-revenue laws on manufacturers of the different classes of products. The increase of \$28,069,956 in

miscellaneous expenses between 1890 and 1900 is not disproportionate to the general growth of the industry, as would first appear, because the item includes internal-revenue tax, which was increased by the act which took effect June 13, 1898. From March 3, 1883, to October 1, 1890, the revenue tax on tobacco and snuff was 8 cents a pound, and from October 1, 1890, to June 13, 1898, it was 6 cents; during the time covered by this report it was 12 cents.

Table 13 is a comparative summary for chewing and smoking tobacco and snuff, by states and territories, 1890 and 1900.

<sup>1</sup>Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 17.)  
<sup>2</sup>Includes establishments distributed as follows: Alabama, 1; California, 1; Colorado, 2; Iowa, 2; Massachusetts, 1; Nebraska, 2.  
<sup>3</sup>Includes establishments distributed as follows: Alabama, 1; Arizona, 1; Delaware, 1; Indiana, 1; Iowa, 1; Kansas, 1; Massachusetts, 2; Texas, 1; West Virginia, 2.

This branch of the industry was less widely distributed than the manufacture of cigars and cigarettes. Only 23 states were represented in 1900; the returns from 6 of these were not separately tabulated, because they included fewer than 3 establishments each. Missouri, Kentucky, North Carolina, Virginia, and New Jersey, in the order named, were the leading 5 states in value of products, their combined output being valued at \$72,166,599, or 69.6 per cent of the total. Michigan, Minnesota, Ohio, Pennsylvania, and Virginia showed a decrease in value of products from 1890 to 1900, due to practically the same causes observed as producing a decrease in value of products for individual states in cigar and cigarette manufacture. Among the leading producers, New Jersey showed the greatest percentage of increase for the decade in both capital and value of products, this being due to the policy of a large corporation in concentrating the manufacture of certain forms of tobacco at Jersey City.

Of the capital invested in this branch of the industry in 1900, land constituted 4.4 per cent of the total reported; buildings, 14.5 per cent; machinery, tools, and implements, 13.9 per cent; and cash on hand and sundries, 67.2 per cent. Of miscellaneous expenses, rent

of offices, insurance, interest, internal-revenue tax and stamps, repairs, advertising, and other sundries constituted 99.1 per cent.

Table 14 shows the cost of materials and the per cent each class is of the total for 1900.

TABLE 14.—CHEWING AND SMOKING TOBACCO AND SNUFF: COST OF MATERIALS, 1900.

	1900	
	Amount.	Per cent of total.
Total.....	\$35,038,287	100.0
Purchased in raw state.....	28,628,161	87.4
Purchased in partially manufactured form <sup>1</sup> .....	10,838,820	30.9
Fuel.....	368,652	1.1
Rent of power and heat.....	8,468	( <sup>2</sup> )
Freight.....	194,188	0.6

<sup>1</sup>Includes "all other materials" and "mill supplies;" the latter is shown separately in Table 17.  
<sup>2</sup>Less than one-tenth of 1 per cent.

Table 15 is a summary for chewing and smoking tobacco and snuff, by states and territories, of the kinds and quantity of materials and products for the calendar year 1900, as compiled from the reports of the Commissioner of Internal Revenue.

According to this table the greatest 5 producers were Missouri, North Carolina, Kentucky, Virginia, and New Jersey, in the order named. These states together produced 206,663,178 pounds, or 68.7 per cent of the total output of the United States. They do not quite correspond in relative position with the 5 states which are first in value of products, because of the difference in form and value of their manufactures.

St. Louis, Mo.; Louisville, Ky.; Winston, N. C.; Richmond, Va.; Middletown, Ohio; Jersey City, N. J.; Martinsville, Va.; Petersburg, Va.; Danville, Va.; and Detroit, Mich., were the leading 10 cities in the manufacture of plug chewing tobacco in 1900, arranged according to the magnitude of their production.

In the manufacture of fine-cut chewing tobacco, Jersey City, N. J.; Chicago, Ill.; Detroit, Mich.; New York, N. Y.; Rochester, N. Y.; Milwaukee, Wis.; Covington, Ky.; Caldwell, N. J.; Utica, N. Y.; and Albany, N. Y., were the leading 10 cities.

Durham, N. C.; Baltimore, Md.; New York, N. Y.; Cincinnati, Ohio; Chicago, Ill.; Jersey City, N. J.; St. Louis, Mo.; Milwaukee, Wis.; Richmond, Va.; and Detroit, Mich., were the greatest 10 producers of smoking tobacco.

The leading 10 cities in the manufacture of snuff were Philadelphia, Pa.; Helmetta, N. J.; Baltimore, Md.; Nashville, Tenn.; Jersey City, N. J.; Clarksville, Tenn.; Chicago, Ill.; Lynchburg, Va.; Pittsburg, Pa.; and Spotswood, N. J.

Table 16 shows the aggregate quantity of chewing and smoking tobacco and snuff withdrawn from the warehouses of manufacturers and importers for domes-

tic consumption for each fiscal year from 1863 to 1900, inclusive, as shown by the report of the Commissioner of Internal Revenue, 1900.

TABLE 16.—AGGREGATE QUANTITY OF CHEWING AND SMOKING TOBACCO AND SNUFF WITHDRAWN FOR CONSUMPTION AND TAX-PAID, FOR EACH FISCAL YEAR FROM 1863 TO 1900, INCLUSIVE.

[Compiled from report of Commissioner of Internal Revenue, 1900.]

1881.....	147,013,405	1900.....	293,894,453

<sup>1</sup> From September 1, 1862.

It will be seen that the quantity produced, as shown by Table 15, does not correspond with the last item of Table 16. The same reasons assigned for a similar discrepancy shown in cigars and cigarettes apply to chewing and smoking tobacco and snuff.

Table 17 is a detailed summary for this branch of the industry, by states and territories, for the census year 1900.

MANUFACTURES.

<sup>1</sup> Includes establishments distributed as follows: Florida, 1; Georgia, 1; Illinois, 1; Indiana, 1; Maryland, 2; South Carolina, 1; Wisconsin, 2.  
<sup>2</sup> Includes establishments distributed as follows: Connecticut, 2; Indiana, 1; New York, 2; Wisconsin, 1.  
<sup>3</sup> Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. (See Table 20.)

The statistics for this branch of the tobacco industry were first shown at the census of 1890, and there are, therefore, no statistics earlier than those shown in Table 18 available for comparison. Tobacco stemming and rehandling is an industry requiring small expenditure of manufacturing forces, and its character is well described by the terms of its classification. It consists principally in sizing the leaves and sorting them as to shade, general character, and quality; stemming and drying them for export; and treating them by fermentation and other processes according to the requirements of each manufacturer's trade.

In 1900 there were 8 states having more than three establishments each. The industry was largely limited to the states of Virginia, Kentucky, Ohio, Tennessee, and New York, in that order. These 5 states combined represented \$17,093,056, or 89.5 per cent of the total value of products. The industry was, therefore, well localized within the tobacco-growing districts.

Of the capital invested in stemming and rehandling of tobacco, 2.7 per cent was in land; 7.9 per cent in

buildings; 3.5 per cent in machinery, tools, and implements; and 85.9 per cent in cash and sundries.

Table 19 shows the cost of materials and the per cent each class is of the total, 1900.

TABLE 19.—TOBACCO, STEMMING AND REHANDLING: COST OF MATERIALS, 1900.

	1900	
	Amount.	Per cent of total.
United States.....	\$14,198,349	100.0
Purchased in raw state.....	13,790,693	97.1
Purchased in partially manufactured form <sup>1</sup> .....	262,018	1.9
Fuel.....	50,588	0.4
Rent of power and heat.....	3,693	( <sup>2</sup> )
Freight.....	91,362	0.6

<sup>1</sup> Includes "all other materials" and "mill supplies;" the latter is shown separately in Table 20.  
<sup>2</sup> Less than one-tenth of 1 per cent.

Table 20 is a detailed summary, by states and territories, for the census year ending May 31, 1900.

## MANUFACTURES.

## HISTORICAL AND DESCRIPTIVE.

The cultivation of tobacco and the use of its manufactures are of such antiquity that authentic history does not record their beginnings. The claims of certain European and Asiatic countries to an acquaintance with the plant prior to the discovery of America by Columbus are not supported by accepted history nor satisfactorily demonstrated by the researches of the antiquarian or the archæologist. It is fairly well settled that tobacco is indigenous to the Western Hemisphere, and that the aborigines practiced its cultivation and use from remotest times. Europeans learned its nature and effects from the American savage and spread the knowledge to the rest of the world. In November, 1492, two sailors sent by Columbus into the interior of Cuba returned with accounts of having seen the natives carrying firebrands and exhaling smoke from their mouths and nostrils. Investigation revealed that the firebrands were made from the leaves of tobacco, rolled and burned in a sheath of Indian corn, and that the smoke was inhaled for sensations of pleasure and exhilaration. The instrument used for inhaling the smoke was made from hollow cane forked in shape of the letter Y, the small ends being inserted into the nostrils and the large end applied to the burning leaves.<sup>1</sup> The habit of snuff taking among the natives was described first by Roman Pane, a Franciscan, who accompanied Columbus on his second voyage, and the practice of tobacco chewing was first observed by Spaniards on the coast of South America in 1502. Tobacco was con-

sumed in one form or another by the aborigines from Canada to Patagonia, and, especially in the form of smoking, its use was an immemorial custom.

Tobacco was first taken to Europe by Hernandez de Toledo, who introduced it into Spain and Portugal from Santo Domingo in 1559. In the same year it was introduced into France from the Spanish Peninsula by Jean Nicot, the French ambassador at Lisbon.<sup>2</sup> It is said to have been used in Italy as early as 1560. In 1585 it was carried to England by Sir Francis Drake and his companions on a return voyage from Virginia, and Sir Walter Raleigh introduced among the Elizabethan courtiers the fashion of pipe smoking, which spread through England with great rapidity. In 1610 smoking is known to have been practiced as far east as Constantinople. Tobacco was cultivated in Holland in 1615, and in 1620 smoking was introduced into Germany. In 1631 the use of tobacco began in Austria, where it was carried by Swedish troops, and in 1653 it is known to have been used in Switzerland.<sup>3</sup> In a period of three hundred years tobacco has circled the earth on practically every parallel within the limits of civilization. It is known everywhere, except among a few barbaric peoples in inaccessible countries, and exceeds every other narcotic in the universality of its use. It is probably exceeded only by salt in width of distribution and cosmopolitan consumption. The adaptability of the plant to varying climatic conditions has

<sup>2</sup> Penny Magazine, London, Vol. I, 1832, page 148.

<sup>3</sup> Nile's Register, Vol. XV, page 110.

<sup>1</sup> Knickerbocker Magazine, Vol. LIV, 1859, page 148.

been an important factor in its dissemination. While it responds, to the extent of pronounced modifications, to the varying influences of soil, climate, and methods of cultivation, its essential characteristics will develop in the cold climate of Canada or on the arid plains of Java. Certain districts produce tobacco having distinct characteristics just as certain provinces produce varieties of grapes that make distinct types of wine. Great diversity of taste is also shown among the people of different nations, in their demand for the different types of tobacco grown in various parts of the world, and it is natural, therefore, that the commodity should become one of importance in international trade. In foreign countries its cultivation and manufacture are frequently made government monopolies, and in some its cultivation is prohibited.

The first tobacco cultivated by a European within the present limits of the United States was grown by John Rolfe at Jamestown, Va., in 1612, five years after the settlement of the colony. As early as 1615 the fields, gardens, streets, and public squares of Jamestown were planted with tobacco. It was the one commodity which sustained the struggling settlement, because it readily commanded, in reciprocal trade with the mother country, the necessaries of life. It was the medium of exchange and the standard of value. In 1619, 20,000 pounds were shipped to England. The profits were so satisfactory to the growers that even the cultivation of food crops was neglected for that of tobacco, and it was restricted for a time by legislative enactment. In 1621, 60,000 pounds were grown, of which 55,000 pounds were exported to Holland, the shipments being diverted to that country because of the excise levied by England. In England the legislation of the Stuarts and that of Cromwell were alike in opposition to the use of tobacco, and it was almost completely stamped out by the Protectorate. With the Restoration, however, it reappeared, and its consumption has since increased steadily with every year.

In 1731 the combined exports of Virginia and Maryland were 36,000,000 pounds. From 1763 to 1770, the average annual exports from all the colonies amounted to 66,780,000 pounds, and for the four years immediately preceding the Revolution the average quantity annually exported was 100,000,000 pounds. During the Revolutionary struggle the exports dropped to an average of 12,000,000 pounds annually.

The settlers of a new country take with them the customs and pursuits of the old, and the Virginians who settled Kentucky early introduced into the new territory the cultivation of tobacco, which was grown as a commodity in parts of Kentucky and Tennessee as early as 1810 and, prior to 1833, was shipped by boat to New Orleans, where it was purchased for foreign consumption. As the production increased, factories were established for purchasing loose tobacco and stemming it for the English market. The first inspection ware-

houses in the United States had been established in Virginia in 1730. In 1839 similar warehouses were established at Louisville, Ky., and in 1845, at Clarksville, Tenn. With the introduction of such local markets the tobacco trade of the Mississippi Valley developed with considerable rapidity, but always with precision.<sup>1</sup>

In New England some tobacco was grown in the decade ending with 1650, but its cultivation was abandoned until the beginning of the Nineteenth century, when it gradually revived. By 1825 the crop was such as to encourage the establishment of a warehouse at Warehouse Point, Connecticut. About 1833 it was ascertained that a variety, possessing in remarkable degree the fineness of texture, strength of tissue, and smoothness of surface, so desirable for cigar wrappings, could be grown successfully in Connecticut, and the census returns since 1840 show an uninterrupted increase in its cultivation in that state, except at the census of 1890. This single interruption is explained by the influence of legislative enactments affecting the tariff on imported leaf suitable for cigar wrappers. The profits of the industry in Connecticut stimulated the cultivation of tobacco in eastern Pennsylvania, central New York, and later in the Miami Valley of Ohio, and in southern Wisconsin. In 1900 the combined production of Connecticut, Pennsylvania, New York, Ohio, and Wisconsin was 183,849,340 pounds.

Especially in the states of the North, every town of any considerable size has its local cigar factory supplying in part the local demand and extending its trade to neighboring villages and towns in proportion to the aggressiveness of the manufacturer and his ability to succeed against competition. The material used in these local factories consists of small lots of leaf tobacco varying in character, quality, and cost according to the quality of the cigars to be made and according as the material is intended for fillers, binders, or wrappers. Such material is usually purchased from importers, wholesalers, or rehandlers, and in such limited quantities as to be quickly worked up and realized on in the local markets. The live capital involved is, therefore, not necessarily large even in proportion to the magnitude of the business. The selection, preparation, and apportionment of the filler, the cutting of the binders and wrappers, and the binding and wrapping are all done by hand. After binding, the unfinished cigars are usually placed in forms or molds and left for some hours in hand presses until the desired shape has become fixed, when they are ready for wrapping. When wrapped, the cigars are assorted into lots having the same shade, and boxed for sale. The work is usually done in rented rooms, and no capital, as defined by the Census Office, is involved in land and buildings. A set of molds and a hand press constitute the principal equipment. In contradistinction

<sup>1</sup>Tobacco Leaf, Killebrew and Myrick, New York, 1897, pages 3-15.

to this class of establishments, is the large factory, representative of the purely commercial aspect of the industry, housed in a large building whose architecture is typical of the modern factory, located usually in a large city, equipped with modern and expensive machinery, employing thousands of wage-earners, and manufacturing millions of cigars and cigarettes annually.

The first cigars consumed in the United States were imported, but the exact date of the first importation is not known because it was included in miscellaneous merchandise. The separate tabulation of imported cigars was begun in 1804, in which year 4,001,000 were received, principally from the West Indies. The first cigar manufactories in the United States were established in Connecticut in 1810, but it is believed that the household manufacture of cigars had been carried on in the Connecticut Valley for several years prior to that date. After the first factories were established at East Windsor and Suffield, Conn., the industry gradually spread through the state and into the other states of the New England group. By 1856, 600 persons were employed in making cigars at various points from Springfield, Mass., to Middletown, Conn. In 1860 the Connecticut Valley had 45 factories, with capital approximating \$400,000; 731 wage-earners, \$274,911 for wages; \$381,000 for cost of materials; and \$1,000,000 for value of products. In 1870 Connecticut alone had 235 factories, whose products approximated \$1,150,000 in value.<sup>1</sup>

Kentucky followed Connecticut in the establishment of cigar factories. As early as 1816 a factory is said to have been established at Maysville. The industry gradually diffused through the state and into Ohio and Tennessee. In 1825 comparatively small factories were found more or less widely scattered through New York and Pennsylvania, and by 1840 factories in considerable number were in operation in New York, Pennsylvania, Maryland, and Virginia. The first cigars made in the United States were almost exclusively the product of domestic leaf, but the importation of Cuban tobacco began early in the history of the industry, and by 1847 had assumed such proportions as to be tabulated in the customs returns. The early manufacturers in the United States had to contend against the importation of cheap cigars from Germany, where their manufacture and consumption date from 1796. The tariff acts of 1861, 1862, and 1864 prevented the importation of the German product, and in consequence the industry in the United States received such an impetus that it has continued in practically uninterrupted growth to the present time.<sup>2</sup> The first internal-revenue law laying a tax on cigars and other forms of manufactured tobacco, was passed to meet in part the exigencies of the Civil War, and took effect July 1, 1862. By this act the

revenue tax on cigars varied from \$1.50 to \$3.50 per thousand, according to value. The organization of the Bureau of Internal Revenue for the collection of taxes under the elaborate system of excise, dates from the act of 1862, and statistics of all forms of tobacco since that time are more complete and reliable than formerly. No very large factories were in existence prior to 1870. In the decade ending with 1880, however, extraordinary prosperity attended the industry; the first large manufactories were then established and commercial cigar manufacture was outlined and became fixed.<sup>3</sup>

Within the last few years both the cigar and the cigarette manufacture have been revolutionized by machinery. As cigar making is widely diffused in the form of numerous small establishments in which the work is done by hand, the utilization of modern machinery in the manufacture of cigars is not as general as in that of cigarettes, which is concentrated in large factories. Four cities, namely, New York, N. Y.; Richmond, Va.; Durham, N. C.; and Rochester, N. Y., produce about 94 per cent of all the cigarettes manufactured in the United States, and practically all are machine made. Considering the large number of very small cigar factories in the United States, comparatively few establishments of this class are sufficiently large to make a complete equipment of modern machinery a paying investment. Taking the largest factories, however, as representative of the application of modern machinery to the industry, it is a fact that both cigar and cigarette manufacturers are utilizing some of the greatest contributions of genius to the lessening of the world's work. Everything, from the stemming of the leaf to the payment of wages to the employees of the factory, is done by machinery. In a modern cigarette factory the prepared tobacco and the sheets of paper used for wrappings are fed to machines which cut the paper into proper size for the wrapper, gum its edge, measure the exact quantity of tobacco needed for each cigarette, wrap it, make the edges of the wrapper adhere, cut the ends, and pack the cigarettes in boxes. In the manufacture of cigars, the prepared filler is placed in the hopper of a machine which apportions the quantity necessary for each cigar, places it in the binder spread to receive it by the operator of the machine, and rolls it. The wrapper is subsequently added by hand or by machinery.

In the last quarter-century the manufacture and consumption of cigarettes in the United States have grown with marvelous rapidity. In 1875, approximately 40 millions, and in 1900, 3,260 millions were consumed, an increase of more than eightyfold in twenty-five years. Much of the popularity of cigarette smoking has its origin in business and social conditions which evolve and govern habits of living. For many years there has been an increasing demand for tobacco in a form that

<sup>1</sup> United States Tobacco Journal, special century issue, 1900, pages 33-36.

<sup>2</sup> Ibid.

affords a short, inexpensive smoke, producing immediate effects. The cigarette is made from a specially mild tobacco, and the consumer almost invariably inhales the smoke, which comes in contact with the delicate membranes of the respiratory tract. In this way the active principle of the tobacco is quickly taken into the circulation, producing immediate physiological results. The tobacco selected is usually of a very light shade, which comes from the variety of the plant, the district in which it is grown, and methods of curing, or all these in combination. Secret processes of bleaching are said to be used by some manufacturers. Harshness may sometimes be subdued into desired mildness by dipping or soaking the tobacco in water slightly acidulated with hydrochloric acid. The selecting, blending, saucing, and general methods of treatment are in accordance with the secret formula of each establishment.

The crude hand manufacture of chewing and smoking tobacco and snuff from the natural and unflavored leaf has grown to the modern manufacture of a multitude of forms, which are the products of elaborate systems of selection, blending, fermentation, flavoring, and saucing, designed to satisfy the tastes of the various classes of consumers. As to form, there are two general classes of smoking tobacco put upon the market, namely, the granulated or flake, and the cut or shredded forms. The former is produced by granulating machines of different styles and varying capacity, in which the breaking and sifting principles predominate. The latter class is produced by feeding the prepared tobacco, flavored and gummed, into machines which first compress it and, in turn, feed it to rotating or vertically reciprocating knives, which shred it to any desired fineness; it is then dried and "bulked," after which it is packed in paper, foil, cloth, tin, or glass packages in a multitude of sizes and styles.

The cost of producing smoking tobacco has been greatly lessened within the last few years by the invention and introduction into the large factories of ingeniously constructed machinery to do the packing. The prepared tobacco and the sheet of paper in which it is to be wrapped are fed to a machine simultaneously; the result is a neatly wrapped package ready for the shelves of the retailers. Between thirty and forty thousand packages are turned out by a single machine in a day of ten hours. A form of smoking tobacco known as cut plug is popular with a large class of consumers. It is a form of shredded tobacco, but made more compact by greater pressure. After the leaf is prepared (sauced and gummed) it is pressed into cakes of desired thickness by hydraulic or steam power presses. The cakes are then cut into plugs of desired width by machines not unlike those used in paper mills for cutting paper. The plugs are next run through machines with vertically-reciprocating knives which cut them into

transverse sections ready for packing in layers in tin boxes.

The manufacture of plug chewing tobacco is, compared with that of other forms, a simple process. After the preparation of the filler, it is pressed by hydraulic or steam power presses into cakes or plugs of varying width, length, thickness, and style, after which it is wrapped and boxed. Fine-cut chewing tobacco is made by machinery very similar to that employed in manufacturing smoking tobacco, the leaf being cut into much finer shreds and sauced or "cased" according to the different formulæ of different establishments.

The making of snuff is the most complicated of all the processes of tobacco manufacture. This article, as found on the market, may be roughly divided into two classes, namely, dry and moist, each of which varies greatly in quality. Snuff is sometimes manufactured in connection with cigars and chewing tobacco, as it affords an opportunity to utilize the parts of the leaf not consumed in those products. The material for dry snuffs is first dampened and put through cutting machines, which chop it finely. It is then subjected to a high temperature and rendered perfectly dry, when it is ready for grinding. The grinding machines preserve much of the principle governing the first manufacture of snuff, which was reduced to a rough powder by pounding or grating. The commonest form of grinding machine consists of a receptacle shaped like the frustum of a cone inverted. A set of rollers of corresponding inclination revolve close to the inner surface, grinding the tobacco between to a fine powder. The finished article is packed by machine packers into bladders, tin cans, earthenware jars, glass tumblers, etc. Scotch, Irish, and Welsh snuffs are the commonest forms of the dry class.

Moist snuffs are of infinite variety. The material used in their manufacture is moist when ground, and is not reduced to a fine powder like the dry snuffs. After grinding, the "flour" is subjected to as many different processes and manipulations as there are manufacturers. Many of these involve frequent handling and bulking to control the different stages of sweating or fermentation which gives character to the finished article, darkening it and developing its peculiar flavor. In addition to saucing, fermentation, and manipulation, ingredients are added to flavor and perfume.

The largest tobacco factories are gathering under one roof the manufacture of practically everything that contributes to the tobacco industry. Factories are now fully equipped for manufacturing the tin, paper, cloth, and other packages in which the products are packed for market, as well as boxes or cases in which they are shipped. Equipment for printing and lithographing labels and advertising posters is also an adjunct of a modern factory, so that there is little demand to be supplied by outside establishments.

# MANUFACTURED ICE.

# MANUFACTURED ICE.

By ARTHUR L. HUNT.

The following report presents the statistics concerning the establishments engaged in the manufacture of ice for sale during the census year ending May 31, 1900. Ice produced by mechanical or chemical means is commonly, but not very appropriately, designated as "artificial," to distinguish it from ice produced by nature. Artificial refrigeration consists simply in the removal of heat, and is accomplished by the use of ammonia, either aqua or anhydrous, or some other volatile liquid, such as sulphurous dioxide or ether, which absorbs heat upon evaporation.

The manufacture of ice as an industry existed as early as 1866, but has attained commercial importance only within the past fifteen or twenty years. The industry naturally had its inception in the South, where ice is not harvested in commercial quantities, and where the difficulties and loss attending its shipment from the North precludes its general use, and has extended not only throughout all the Southern states but into the majority of the Northern and Western states. The ice industry, in connection with the operation of cold-storage houses and the introduction of refrigerator cars, has aided greatly in the development of the natural resources of different sections of the United States, and forms a most important factor in the industrial development and progress of not only the Southern states but many of the Northern states. Refrigerator cars insure the safe transportation of perishable articles, and cold-storage warehouses obviate the necessity of their shipment as soon as produced or their consumption as soon as delivered, thus allowing the goods to be held before or after shipment until there

is a market for them. Artificial refrigeration has thus given a great stimulus to the production of early vegetables and small fruits, especially strawberries, in the South and on the Pacific coast. It has also been of great importance to the slaughtering and meat packing industry, facilitating the storage and the handling of dressed meats and making it possible to carry on the operations of this industry throughout the entire year, whereas previously it had been limited to the winter season.

The statistics presented in this report relate exclusively to establishments which manufactured ice for sale. Many of these establishments, however, operate cold-storage houses in connection with their ice plants, and the receipts for storage are included in the total value of products. The report does not include the statistics of establishments which manufactured ice for their own consumption, such as breweries, meat and provision cold-storage houses, chemical factories, and various other establishments.

Table 1 presents in summarized form the statistics of the industry as returned at the censuses of 1870 to 1900, inclusive, with the percentages of increase for each decade. The totals for 1900 include returns from 12 establishments, the reports for which were not secured in time to be included in the general report upon this industry, and therefore these totals do not agree with those given in Parts I and II, Manufactures. Table 2 shows the totals for the industry for 1900 as given in the general report, and also the totals for the additional reports received, a combination of the two making the totals shown in Table 1

Table 1 indicates the remarkable progress which has taken place in this industry during the thirty years ending with 1900. Statistics of the manufacture of ice first appear in the census of 1870, when returns were received from 4 establishments with a capital of \$434,000 and products valued at \$258,250. In 1900 the number of establishments was 787, the capital \$38,204,054, and the value of products \$13,874,513. The growth of the industry is perhaps more forcibly illustrated by the following diagram:

COMPARATIVE GROWTH OF CAPITAL AND PRODUCTS, 1870 AND 1900.

During the period from 1870 to 1880 the number of establishments increased from 4 to 35, the capital from \$434,000 to \$1,251,200, and the value of products from \$258,250 to \$544,763. A comparison of the figures reported for 1890 with those reported for 1880 indicates that most notable progress occurred in this industry during this decade. The number of establishments increased from 35 to 222; the capital from \$1,251,200 to \$9,846,468; and the value of products from \$544,763 to \$4,900,983. During the past decade the industry has made still greater advances, although the per cent of increase is not as large as that shown during the preceding decade. The number of establishments increased from 222 to 787, an increase of 565, or 254.5 per cent; the capital from \$9,846,468 to \$38,204,054, an increase of \$28,357,586, or 288 per cent; and the value of products from \$4,900,983 to \$13,874,513, an increase of \$8,973,530, or 183.1 per cent.

A comparison of the average capital and value of products per establishment for the several censuses sheds further light upon the development of the industry since 1870. In that year the average capital per establishment was \$108,500 and the average value of products \$64,563. These averages are higher than for any of the subsequent censuses, probably because the four establishments included one which reported products valued at nearly \$250,000. This establishment had been erected in New Orleans in 1866 and was the first ice factory of importance built in the United States. At this time nearly all of the natural ice used in New

Orleans came from Boston, and, on account of the distance, difficulties of shipping, and loss by melting, the price was excessively high, ranging from \$15 to \$20 per ton. Although the manufactured ice was crude and often very poor, the cost of production was excessive, owing to the experimental nature of the process, the imperfect knowledge of the operators, and the loss of ammonia by leakage. These circumstances combined with the excessive price of natural ice to keep the price for manufactured ice correspondingly high. In 1880 the average capital per establishment decreased to \$35,749 and the average value of products to \$15,565. The decade between 1870 and 1880 may be looked upon as the incipient and experimental stage of the industry. A number of small-capacity plants were installed, usually in Southern towns of considerable population, where the manufactured product would have to compete with natural ice only to a very limited extent. In this way a demand for ice was created and supplied. In many instances the surplus was sent to neighboring communities, and led generally to the establishment of plants in these localities also. Later the industry gained a foothold in the cities where natural ice was used to some extent by the wealthy families and by a few of the larger dealers in perishable products.

The decade from 1880 to 1890 witnessed a rapid growth in the industry and demonstrated that it was possible to manufacture ice on a scale commensurate with the needs of the community in which the plant was located. Thus the industry became firmly estab-

lished. Small establishments began to increase their capacity and to install larger refrigerating machines. The average capital per establishment increased to \$44,353, or 24.1 per cent, and the value of products to \$22,077, or 41.8 per cent. The decade from 1890 to 1900 witnessed a still further increase in the productive capacity, resulting in an increase in the average capital per establishment to \$48,544, or 9.5 per cent. There was a decrease, however, in the average value of products from \$22,077 to \$17,630, or \$4,447 per establishment, caused, in part at least, by a decrease in price to the consumer, which resulted from the general reduction in the cost of production, due to the increasing knowledge of refrigerants and refrigerating processes.

The corporate form of organization predominates in this industry. Of the total number of establishments reporting, 475, or 60.4 per cent, were operated by incorporated companies. Of the remainder, 179, or 22.7 per cent, were conducted by individuals, and 133, or 16.9 per cent, by firms or limited partnerships.

Table 3 presents, by states and territories, the number of ice-manufacturing establishments as returned at the censuses of 1870 to 1900, inclusive, together with the increase during the decade.

Table 3 indicates in a striking manner the growth of the industry since 1870. In 1870 all 4 of the establishments reporting were located in the Southern states, and the same is true of nearly all of the 35 plants returned at the census of 1880. From 1880 to 1890 the number of establishments increased rapidly and the industry extended to the Middle, Central, Western, and Pacific states, supplementing the supply of ice furnished by nature. Although, between 1890 and 1900, the number of establishments increased remarkably throughout the South, the greatest and most striking increases occurred in a few of the Middle and Central states, namely, Pennsylvania, Indiana, New York, and Ohio. In 1890 Ohio was the only one of these states which reported as many as 10 ice plants, and the number in each of the other states, with the exception of Pennsylvania, was under 5. At the present census not one of these states reported less than 40 ice-manufacturing plants, and in Pennsylvania the number reached 73. This remarkable growth of the industry in the North is largely accounted for by the fact that the process of manufacture, through the perfection of the refrigerating machines, the mechanical appliances used, and the general economy of the plant, has reached a point where the manufactured product can be produced at a cost which makes it possible to compete successfully with the natural product.

It is interesting to compare the number of establishments in the Southern states with the total number in the United States for 1890 and 1900. These 15 states comprise a little less than one-third of the 52 states and territories of the United States, and the comparison shows the growth of the industry in the North and West. In 1890, 165, or 74.3 per cent of the total number, were located in the South. In 1900 the number in the South increased to 386, an increase of 133.9 per cent, but formed only 49 per cent of the total number of establishments.

In no state or territory has there been a decrease in the number of establishments. The increase in the total number from 1890 to 1900 was one hundred and

forty-one times the total number reported for 1870, over sixteen times that returned for 1880, and over two and one-half times that reported for 1890. The leading 10 states in 1900, ranked according to the number of establishments, were: Texas, 77; Pennsylvania, 73; Indiana, 47; Ohio, 42; New York, 41; Louisiana, 36; Florida, 35; Georgia, 32; Missouri, 31; and Kentucky, 31. The following states reported no ice-manufacturing establishments: Idaho, Maine, Massachusetts, Michigan, Minnesota, Montana, Nevada, New Hampshire, North Dakota, South Dakota, Vermont, Wisconsin, and Wyoming.

In the manufacture of ice there are two systems used, commonly known as the "compressor" and the "absorption" systems. The compressor system, which is by far the more common of the two, involves three successive steps, respectively called compression, condensation, and expansion. In this system anhydrous ammonia, or ammonia which contains no water, in the gaseous form is subjected to a pressure of from 125 to 175 pounds per square inch, by the use of a pump employing steam or other power. At the beginning the gas contains a certain amount of heat, and substantially none of this is lost by compression. The gas is next reduced to the liquid state by condensation. This is performed by passing the ammonia through coils of pipe, the pipes being in contact with cold water or some other cooling medium. The excess of heat is thus given up, and the ammonia, reduced to the liquid state, is then caused to expand or become gaseous in coils of pipe which are in contact with the water to be frozen. This reduces the temperature of the ammonia gas below the freezing point of water, and the ammonia absorbs from the water to be cooled the heat which was taken from the former during condensation. This of necessity results in the freezing of water, owing to the well-known fact that if two substances of different temperatures are allowed to come in contact with each other, the warmer body will impart its heat to the colder, until the temperatures of the two are equalized. This is the theory of all refrigerating processes. The ammonia, having completed its cooling work, is then returned to the compressor where it may be reused repeatedly. There is, however, a small loss during each cycle of operations, and the supply must be replenished at intervals.

In the absorption system an aqueous solution of ammonia is used, the process involving four successive steps: the generation of gas, condensation, expansion, and absorption. The application of heat to the aqua ammonia converts it into a gas, and raises the pressure to from 120 to 160 pounds per square inch. The ammonia is then condensed, or reduced to liquid form by being conducted through pipes which are in contact with cold water. The next step is the expansion, which is usually accomplished as in the compressor system. The ammonia is now changed from a liquid to a gas, and,

being greatly reduced in temperature, absorbs heat from the pipes, thus producing ice or refrigeration.<sup>1</sup>

Table 4 presents, by states and territories, the number of establishments in 1900 using the compressor and the absorption systems, and the per cent of each to the total number.

TABLE 4.—NUMBER OF ESTABLISHMENTS USING THE COMPRESSOR AND THE ABSORPTION SYSTEMS, AND THE PER CENT OF EACH TO THE TOTAL NUMBER, BY STATES AND TERRITORIES; ARRANGED GEOGRAPHICALLY: 1900.

From Table 4 it appears that of the 787 establishments reporting, 571, or 72.6 per cent, used the compressor system, and the remainder, 216, or 27.4 per cent, employed the absorption system. These figures show that the compressor system is the one in general use. It is in fact superseding the absorption, which is the older of the two processes. The latter, however, is still used in the smaller plants and warm climates, as its

<sup>1</sup> Artificial Ice Making and Refrigeration, by Louis M. Schmidt, pages 5-8.

operation requires less machinery and a less complicated arrangement of appliances. In three of the Southern states—Florida, Kentucky, and Louisiana—the number of establishments using the absorption system exceeded the number employing the compressor system. In West Virginia, Georgia, and New Mexico the number employing each system was the same, but in the majority of the remaining states, with the single exception of Colorado, the number using the compressor system was far in excess of the number employing the other system. It will also be noticed that a number of states reported no establishments using absorption machines. The following states reported plants using both systems: Colorado, 1; Kansas, 1; Kentucky, 2; Louisiana, 1; Mississippi, 1; Missouri, 1; Tennessee, 2. These latter establishments were classified according to the number or capacity of the compressor or absorption machines used.

Table 5 is a comparative summary of capital for 1890 and 1900, with the per cent of each item to the total, and the per cent of increase for the decade.

TABLE 5.—COMPARATIVE SUMMARY, CAPITAL: 1890 AND 1900.

	1900		1890		Per cent of increase.
	Amount.	Per cent of total.	Amount.	Per cent of total.	
Total.....	\$38,204,054	100.0	\$9,846,468	100.0	288.0
Land.....	4,679,379	12.3	1,595,360	16.2	193.3
Buildings.....	7,387,014	19.3	1,338,652	13.6	451.8
Machinery, tools, and implements.....	22,852,158	59.8	5,939,719	60.3	284.7
Cash and sundries.....	3,285,503	8.6	972,737	9.9	237.8

As shown by Table 5, the increase between 1890 and 1900 in the total capital employed in the manufacture of ice was \$28,357,586, or 288 per cent. Of the total value of capital reported, the value of machinery, tools, and implements, including refrigerating apparatus and machinery, boilers, tanks, air compressors, small engines, pipe coils, ice receptacles, and all other apparatus and accessories required, constituted the principal item both in 1890 and 1900, amounting to \$5,939,719 in 1890 and \$22,852,158 in 1900, an increase of \$16,912,439, or 284.7 per cent. The per cent of this item to the total capital was substantially the same for each year. The value of buildings, the next largest item, increased from \$1,338,652 to \$7,387,014 during the decade, an increase of \$6,048,362, or 451.8 per cent. The value of land increased from \$1,595,360 to \$4,679,379, an increase of \$3,084,019, or 193.3 per cent. It constituted, however, a smaller proportion of the total capital in 1900 than in 1890. The value of buildings, on the other hand, not only exhibited a striking increase, but constituted a larger proportion of the capital in 1900 than in 1890. This increase was probably due to the erection of cold-storage plants operated in connection with the manufacture of ice, to the increase in the ice-storage capacity, and to the generally

increased productive capacity of the plants. Cash and sundries, including cash on hand, bills receivable, unsettled ledger accounts, raw materials, stock in process of manufacture, finished products on hand, and other sundries formed the smallest item of the total capital, amounting to \$972,737 in 1890, and to \$3,285,503 in 1900, an increase of \$2,312,766, or 237.8 per cent, and constituted 8.6 per cent of the total capital in 1900, or nearly the same per cent as in 1890. The above figures do not represent the capital stock of any of the corporations, but include only the actual value of the plants, together with the amount necessary for working capital.

The schedule of inquiry adopted for 1890 was the first which contained questions designed to show the cost of manufacture other than for wages and materials. The questions of the Twelfth Census relating to miscellaneous expenses were made as nearly uniform as possible with those of the previous census, and the returns are shown in Table 6, together with the per cent of each item to the total.

TABLE 6.—MISCELLANEOUS EXPENSES: 1900.

	Amount.	Per cent of total.
Total.....	\$1,779,890	100.0
Rent of works.....	116,026	6.5
Taxes, not including internal revenue.....	246,340	13.9
Rent of offices, insurance, interest, repairs, advertising, and other sundries.....	1,394,180	78.3
Contract work.....	23,344	1.3

The amount paid for rent of offices, insurance, interest, internal-revenue tax and stamps, repairs of buildings and machinery, advertising, and all other sundries not reported under the head of materials, etc., was the principal item, and constituted 78.3 per cent of the total miscellaneous expenses. This amount does not include expenditures for new equipment, machinery, and other apparatus. The amount of interest in this item does not include the interest paid on bonds by incorporated companies, but only the small sums expended during the year for money or credit necessary to conduct the business. The remaining items under miscellaneous expenses formed but a relatively small per cent of the total amount reported.

Table 7 shows the cost of the different materials used in the manufacture of ice in 1900, with the per cent of each item to the total cost of materials.

TABLE 7.—COST OF MATERIALS USED: 1900.

	Amount.	Per cent of total.
Total.....	\$3,339,724	100.0
Ammonia.....	359,549	10.8
Anhydrous.....	279,680	8.4
Aqua.....	79,869	2.4
All other materials.....	501,485	15.0
Fuel.....	2,144,316	64.2
Rent of power and heat.....	20,336	0.6
Mill supplies.....	216,333	6.5
Freight.....	97,654	2.9

The total cost of materials in 1900 was \$3,339,724 as compared with \$940,699 in 1890, an increase of \$2,399,025, or 255 per cent. The quantities and values of the different materials used are presented in detail in Table 11, by states and territories.

The manufacture of ice is peculiar in that practically the only materials which affect the cost are those which do not enter into the product, but are used in the generation of the cold necessary for the production of ice. The principal item of expense is the cost of fuel used to propel the machinery. In 1900 this was \$2,144,316, or 64.2 per cent of the total cost. No attempt was made to ascertain the number of tons of coal represented by this amount. Ammonia, anhydrous and aqua, is the principal material used as a refrigerant. The cost of ammonia was \$359,549, or only 10.8 per cent of the total cost of materials used. The cost of anhydrous ammonia was \$279,680, or 8.4 per cent of the total cost of materials, and the cost of aqua ammonia was \$79,869, or 2.4 per cent of the total cost of materials.

The item "other materials" included the amounts expended for brine, made either with sodium chloride (common salt) or chloride of calcium, and also the amount expended for water consumed, and constituted the remainder of the materials used directly in connection with the production of ice, the common salt and the chloride of calcium assisting in refrigeration, and the water entering into the product. The quantities

of sodium chloride, chloride of calcium, and water were not ascertained and the cost of each was not given separately. Included also with "other materials" is the cost of anhydrous sulphurous dioxide and ether, which are used to some extent as refrigerants in place of ammonia in the Pictet machine, so called from its inventor, Professor Pictet, of Geneva, Switzerland. There were 7 establishments using anhydrous sulphurous dioxide, distributed as follows: California, 1; Kentucky, 3; New Jersey, 1; Pennsylvania, 1; Texas, 1. There was only 1 establishment using ether. The total quantity of anhydrous sulphurous dioxide used was 13,870 pounds, costing \$2,540, an average of 18.3 cents per pound. The cost of ether was given as \$350. A combination of these amounts with the sum expended for ammonia shows that the total amount expended for refrigerants was \$362,089, or 10.8 per cent of the total amount expended for materials used in the manufacture of ice.

As stated above, the ammonia used in artificial refrigeration is of two kinds, anhydrous and aqua. In the compressor machines, anhydrous ammonia is used exclusively, but in the absorption machines both aqua and anhydrous ammonia are used. Table 8 shows, by states and territories, the quantity and cost of each variety of ammonia used in 1900, including the anhydrous ammonia used in the compressor system, and the anhydrous and aqua ammonia used in the absorption system, with the average cost of each per pound.

TABLE 8.—QUANTITY AND COST OF AMMONIA USED; QUANTITY, COST, AND AVERAGE COST PER POUND OF ANHYDROUS AMMONIA USED IN THE COMPRESSOR SYSTEM; AND QUANTITY, COST, AND AVERAGE COST PER POUND OF ANHYDROUS AND OF AQUA AMMONIA USED IN THE ABSORPTION SYSTEM; BY STATES AND TERRITORIES; ARRANGED GEOGRAPHICALLY: 1900.

The total cost of ammonia is given as \$359,549 and the total number of pounds as 2,379,989. The cost of the anhydrous ammonia used in the compressor system was \$249,838 and the number of pounds 946,666, or 39.8 per cent of the total number of pounds of ammonia reported for both systems. The average cost was 26.4 cents per pound. The cost of anhydrous ammonia used in the absorption system was 27.1 cents per pound. The total cost of the aqua ammonia used was \$79,869, an average of 6 cents per pound, and the number of pounds was 1,323,454, or 55.6 per cent of the total. The average price for anhydrous and aqua ammonia was secured from the totals of the whole number of establishments from which reports were received, and there-

fore does not indicate the price in any one state or section of the country. The cost and also the quantity used vary considerably in different sections of the country. Furthermore, ammonia is sometimes bought delivered, and it was found impracticable to attempt to separate the amount chargeable to freight. The table, however, reflects in a general way the variations in the price of ammonia in different sections of the country. It appears that the average cost of anhydrous ammonia varied from 22 cents to 40 cents per pound, according to the distance from the source of supply, the average cost being lowest in the Middle and Central states and highest in the Pacific states. The average cost of aqua ammonia varied similarly

from 5 to 9 cents per pound. The quantity of ammonia used depends so much upon its strength and density, upon the type of refrigerating machine used and its condition as to leakage, and also upon the care of the engineers, that an establishment may be obliged to use during one year two to three times the quantity required during the previous year. This statement is necessary in order to obviate erroneous deductions from the figures presented in Table 8.

The total value of products, \$13,874,513, as given in Table 1, for 1900, as compared with \$4,900,983 for 1890, shows an increase of \$8,973,530, or 183.1 per cent, during the past decade. The value of the principal product, ice, amounted to \$13,303,874, and formed 95.9 per cent of the total value of product. The value of other products amounted to \$570,639, and formed 4.1 per cent of the total value of products. This item includes amounts received for cold storage and for the manufacture of bottled goods and soda water, but the amount received for each was not separately ascertained.

Practically all of the ice manufactured in the United States is produced by the can system or the plate system. In the can system distilled water is used, since if the water were not distilled the ice would be opaque, and, in most cases, of a brownish color. Distilled water is furnished by condensing exhaust steam from the refrigerating machine or by condensing live steam. In the plate system a clear ice is made without distilling the water.

In the can system ice may be formed either in stationary cells or in removable cans, the latter being the method in more general use at the present time. If stationary cells are used, all the cells in an entire tank must be emptied at the same time, which necessitates the use of more than one tank in order to make the operation continuous. In the other method the water to be frozen is placed in cans, which are in turn immersed in iron or wooden tanks containing cold brine. The cans can be taken out singly, and after the ice is removed can be filled again with water and replaced in the tank. Thus the process is continuous. The ice is removed either by dropping the can into, or sprinkling

it with tepid water. The time required for the formation of the ice varies from twenty to sixty-six hours, according to the thickness of the mold containing the water to be frozen and the temperature of the brine.

The following table indicates the weight of blocks, size of can, and the time required for freezing:

STANDARD ICE CANS OR MOLDS.<sup>1</sup>

WEIGHT OF BLOCKS.	Size of can.	Time of freezing (with 18° brine).
Pounds.	Inches.	Hours.
50	6 x 12 x 26	20
100	8 x 16 x 32	36
150	8 x 16 x 42	36
200	11 x 22 x 32	60
300	11 x 22 x 44	60
400	11 x 22 x 57	60

<sup>1</sup>Mechanical Refrigeration and Ice Making, the De La Vergne Refrigerating Machine Company.

In the plate system a hollow iron plate is immersed in a tank containing the water to be frozen, and as the plate contains coils for the freezing medium or is filled with brine, the ice is formed on the two outer surfaces. It may be loosened in several ways, according to the system of refrigeration used. The production of ice by the plate system is much slower than by the can system, and for this reason the use of several plates is necessary for a continuous process. The ice cake may be of several sizes, the standard being 16 feet long, 8 feet wide, and 11 inches thick. This system is used chiefly in connection with electric power where the conditions are such that the cost compares favorably with the cost of steam power.

Table 9 shows, by states and territories, the quantity and value of can ice and of plate ice in 1900, with the average value per ton of each, and the per cent which the production of each variety in each state was of the total production of that variety in the United States. Table 9 also includes the returns for one establishment engaged in the manufacture of spray ice—that is, the water is sprayed on pipes and frozen in that manner. The product of this establishment is included in the totals for can ice.

MANUFACTURED ICE.

The total quantity of ice manufactured in the United States, as returned by the 787 establishments reporting, was 4,294,439 tons, valued at \$13,303,874. In addition to this quantity, returns were received from 8 establishments which were engaged primarily in other industries, but which reported the manufacture of ice for sale. These establishments manufactured during the census year 59,206 tons of can ice, valued at \$108,259. If these amounts are added to those given in Table 9, the total quantity of ice reported as manufactured for sale in 1900 is shown to be 4,353,645 tons, valued at \$13,412,133. This does not represent the total quantity manufactured during the census year, as it is probable that many establishments engaged in the manufacture of ice for sale in connection with other industries failed to state that fact, and reported the value of ice under

"all other products." Moreover, as stated above, this total does not include the number of tons produced by companies engaged in other industries but manufacturing ice for their own consumption. Notwithstanding these facts, the number of tons reported may be accepted as fairly representing the quantity of ice manufactured for sale during this period. Of the quantity given in Table 9, 4,139,764 tons, or 96.4 per cent of the total, valued at \$12,863,160, was can ice, and 154,675 tons, or 3.6 per cent, valued at \$440,714, was plate ice. The average value of can ice was \$3.11 per ton and of plate ice \$2.85 per ton. In this connection, however, it should be stated that local conditions, cost of production, and the supply of natural ice cause the value of manufactured ice to vary between very wide limits. The average value per ton, as given in

the above table, represents the value at the plant and is computed from the totals of the whole number of establishments from which reports were received. It can not therefore be regarded as the value in any particular section of the country.

It appears from Table 9 that the largest quantity of ice was manufactured in the Middle states, which reported 1,574,980 tons, valued at \$3,983,498. The group producing the smallest quantity of ice was the New England states, with 40,059 tons, valued at \$131,376. The Southern states, although having nearly one-half of the total number of establishments in the United States, reported a production of only 1,414,158 tons, valued at \$5,291,523, or 32.9 per cent of the total quantity produced. This indicates that the plants in the South were,

as a rule, smaller than those in other sections of the United States.

The leading state in the manufacture of ice in 1900 was Pennsylvania, with a production of 735,018 tons. New York came next, with 457,779 tons. Missouri ranked third, with 285,796 tons; Illinois fourth, with 249,813 tons; Ohio fifth, with 237,750 tons; Texas sixth, with 231,450 tons; Indiana seventh, with 199,184 tons; Louisiana eighth, with 179,716 tons; New Jersey ninth, with 169,755 tons; and Tennessee tenth, with 158,931 tons. The total quantity of ice produced by these 10 states was 2,905,192 tons, or 67.7 per cent of the total number of tons reported for the United States. The number of tons produced in each of these states is shown in the following diagram:

COMPARATIVE PRODUCTION OF MANUFACTURED ICE IN LEADING TEN STATES: 1900.

Table 10 presents the statistics of the cities in the United States having a population of over 20,000 in which there were three or more ice-manufacturing establishments in 1900. Estimates of the consumption of natural ice in several of these cities were secured for comparative purposes, but it was found impossible to

obtain such information in all cases. In this connection attention is called to the fact that where two or more plants located in the same city or town were controlled by the same corporation, firm, or individual, they were counted as one establishment.

MANUFACTURED ICE.

Table 10 indicates that New York city led in the manufacture of ice, having reported 26 establishments and 410,837 tons of ice valued at \$868,239, an average of 15,801 tons per establishment, and an average value of \$2.11 per ton.

Efforts were made to get estimates of the consumption of natural ice in each of the cities included in Table 10. In all cases except New York and Philadelphia the results were, however, too unreliable to be included in this report. In New York it was estimated that the annual consumption of ice is about 5,000,000 tons.<sup>1</sup> If these figures are approximately correct, the manufactured ice consumed during the census year formed 8.2 per cent of the total consumption. Correspondence with several of the leading ice manufacturers indicates that the average cost of production of manufactured ice was approximately \$1.50 per ton and the average wholesale price \$2 per ton, and that the average retail price

varied from 15 to 30 cents per 100 pounds, according to the season of the year. In Philadelphia the annual consumption of ice was estimated at from 1,000,000 to 1,600,000 tons,<sup>2</sup> 342,602 tons of which was represented by the local production of manufactured ice. The average cost of production was approximately \$2 per ton, the average wholesale price \$2.25 per ton, and the average retail price ranged from 20 to 40 cents per 100 pounds, according to the season of the year. In San Francisco from 10,000 to 15,000 tons of natural ice were used, brought from the Sierra Nevada Mountains, but, owing to climatic conditions, the consumption of ice in this city is much smaller than in Eastern cities of the same size. No statistics are available for the remaining cities relative to the consumption of natural ice or to the average cost of production per ton of manufactured ice. In New Orleans, Memphis, Norfolk, Nashville, Dallas, Atlanta, Augusta, Jacksonville, Fort Worth,

<sup>1</sup> Ice and Refrigeration, December, 1901, p. 243.

<sup>2</sup> Ice and Refrigeration, December, 1901, p. 243.

Little Rock, Montgomery, Austin, Birmingham, Charleston, Chattanooga, Columbia, Galveston, Houston, Knoxville, Macon, Mobile, San Antonio, Savannah, Waco, and Wilmington, N. C., manufacturers reported that no natural ice was sold during the census year, the entire quantity consumed being manufactured.

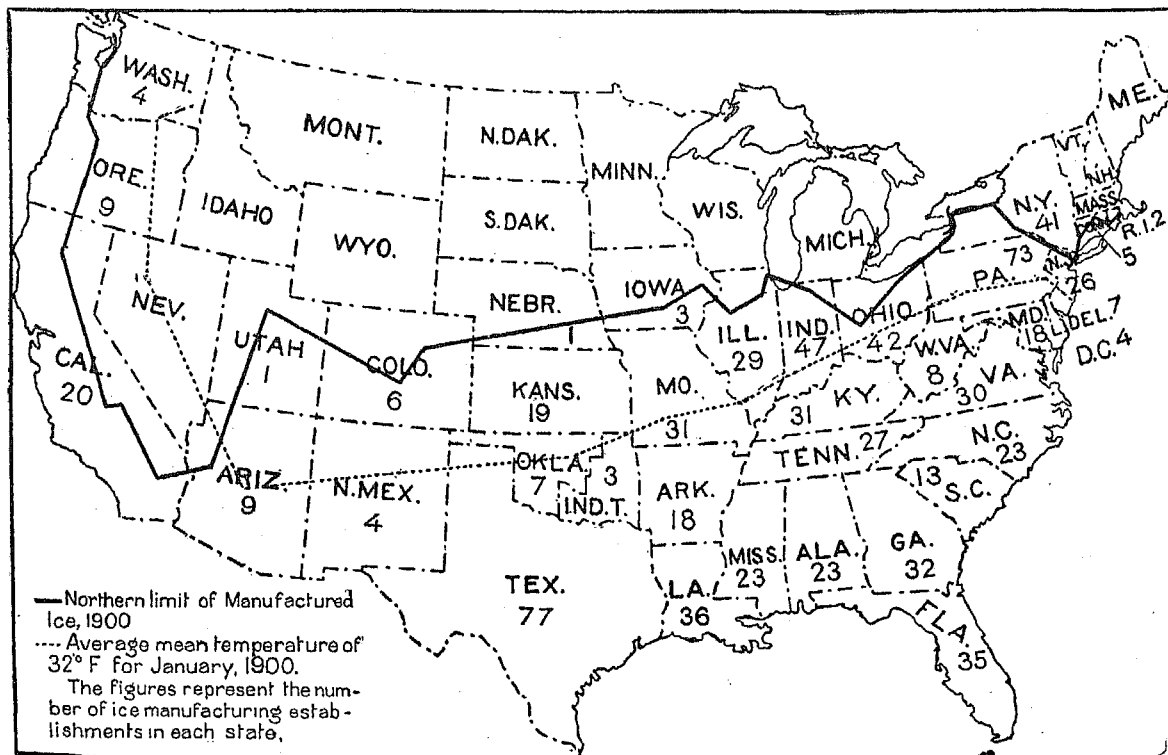

The development of the ice manufacture has naturally had a very close relation to the possibility of procuring natural ice, and there has always been considerable competition between the two products. This is illustrated by the development of the industry in the South. The situation in 1880 is described in the report on the Tenth Census as follows: "For fifteen years efforts have been made to reduce the cost of ice in the South and render her, in a measure, independent of outside sources of supply. Tennessee and Georgia have imported extensively from the Ohio River region by rail. The lower Mississippi has bought in the St. Louis region and Texas has imported by rail. Enterprise has, however, been chiefly in the direction of the manufacture of artificial ice. \* \* \* The cost of production has been reduced to about \$5 per ton in most places, which is a trifle below the rate at which ice can be delivered in Tennessee and Georgia by rail from the Ohio River, and considerably below the cost of the article from Maine, delivered in inland Southern towns. With this advantage in its favor, the business of manufacture is steadily growing at all points at a distance from the seacoast. The prospect is fair that they will soon be independent of outside sources of supply, although it will be many years before the cost to small consumers will fall anywhere nearly as low as in the North. On the seacoast Northern ice still has the preference. It can be

landed more cheaply than the local article can be made, and by purchasing in Maine or Massachusetts the dealers avoid the heavy risks of experimenting with expensive plants and imperfect methods of manufacture. The solitary exception is the city of New Orleans, which, though still buying Northern ice, is nevertheless manufacturing on an extensive scale."

The above statement is interesting in connection with the status of the manufactured-ice industry in Southern cities at the present time. Correspondence with men prominently identified with the ice industry in the South developed the fact that during the year 1900, with the possible exception of a few coast cities, the South depended entirely for her ice supply upon the manufactured product. In the large Southern cities it was stated that the cost of production was approximately \$2 per ton. In the smaller cities and towns, although the cost is in excess of that figure, it is so much reduced that they are now independent of outside sources of supply.

The United States may therefore be divided into three divisions or zones: A southern zone, where the expense of procuring natural ice gave manufactured ice a complete monopoly; a middle zone, where both natural and manufactured ice were sold in competition with each other; and a northern zone, where the low cost of natural ice made its monopoly complete. The southern zone comprises roughly all states south of a line drawn through the northern boundary of North Carolina. The boundary line between the middle and northern zones is indicated by the heavy line upon the accompanying map of the United States.

NORTHERN LIMIT OF MANUFACTURED ICE, 1900.

The most marked change in the industry in recent years has been the exclusion of natural ice from the southern zone and the steadily northward extension of the competitive zone. It is altogether probable that this movement will continue as the cost of production is further reduced. It is stated that under exceptional circumstances ice has been manufactured at as low a cost as 50 or 60 cents per ton. It is probable that at such a cost manufactured ice could compete successfully with the natural product in any part of the country in which there is a demand for ice. The larger plants located in the large cities, during the summer months, when running at full capacity and under favorable conditions, can manufacture ice at from 70 to 90 cents per ton. The average cost for the year, however, will vary from \$1.10 to \$1.50 per ton. The relation of the present northern limit of ice manufacture to the possibility of obtaining natural ice is shown on the map by the broken line connecting the cities which reported an average temperature of 32° for the month of January, 1900.

#### HISTORICAL AND DESCRIPTIVE.

The production of cold by artificial means commenced at a much earlier date than is generally supposed. In the warmer climates, especially in the Eastern countries—India, China, and Egypt—where ice and snow were not available, caves, either natural or artificial, were made use of to deposit food and drinks. It was early discovered that porous receptacles would keep the contents cooler than nonporous. In Egypt and East India the vessels containing the water to be frozen were covered with stalks of corn or sugar cane, which was a crude method of artificial refrigeration. A member of the Royal Philosophical Society of England, for some time a resident of the Indies, has described this method of ice making employed in the East, as follows:

A space of ground of about 4 acres, nearly level, is divided into square plats from 4 to 5 feet wide. The borders are raised by earth taken from the surface of the flat, to about 4 inches; the cavities are filled up with dry straw or sugar-cane haum, laid smooth, on which are placed as many broad shallow pans of unglazed earth as the spaces will hold. These pans are so extremely porous that their outsides become moist the instant water is put into them. They are smeared with butter on the inside to prevent the ice from adhering to them, and this it is necessary to repeat every three or four days. It would otherwise be impossible to remove the ice without either breaking the vessel or spending more time in effecting it than could be afforded where so much is to be done in so short a time. In the afternoon these pans are all filled with water by persons who walk along the borders or ridges. About 5 o'clock in the morning they begin to remove the ice from the pans, which is done by striking an iron hook into the center of it, and by that means breaking it into several pieces. If the pans have been many days without smearing, and it happens that the whole of the water is frozen, it is almost impossible to extract the ice without breaking the pans. The number of pans exposed at one time is computed at about 100,000, and there are employed in filling them with water in the evenings and taking out the ice in the mornings about 300 men, women, and children. The water is taken from a well contiguous to the spot. It is necessary that the

straw be dry. When it becomes wet, as it frequently does by accident, it is removed and displaced.<sup>1</sup>

References are found in the works of many ancient Greek authors indicating that some of the principles of artificial refrigeration were understood by the Greeks and practiced by them in cooling wine, water, and various other drinks. It also appears that they understood the present East Indian custom of using porous vessels. The Egyptians were accustomed to allow jars of boiling water to remain on the house roofs over night, and in the morning the jars were moistened with water on the outside, bound with grass or plants, and put in trenches. The discovery of the principle that warm or hot water exposed to the air is susceptible of greater evaporation than cold water, is generally ascribed to Nero, although it appears that Aristotle understood this principle, since he relates that if it was desired to cool water suddenly, it was customary to expose it first to the sun's rays. Medieval history indicates that the custom of cooling drinks spread from Greece and Italy to France and western Europe about the end of the Sixteenth century. At this time it was the custom to preserve snow and ice in cellars, to be used in cooling drinks during the summer months. This custom was at first looked upon as effeminate and luxurious, but by the end of the Seventeenth century the practice must have been common in France, as there were many who made a business of dealing in snow and ice. It is stated that saltpeter for refrigerating purposes was first used by the Italians about 1550. The liquor or liquid to be cooled was put into a little-necked bottle, which was immersed in a receptacle filled with cold water. Saltpeter was then added to the water of the outer vessel, and the bottle containing the water or wine to be cooled was twirled around on its axis. It was considered that the proportion of saltpeter to water should be one to four or five. The practice of mixing snow or ice with saltpeter or other salts to produce cold seems to have been well known early in the Seventeenth century, being referred to by several contemporary writers of that period. It is mentioned by Bacon, who stated that common salt could be used instead of saltpeter.

The development of ice manufacture has always had a very close relation to the possibility of procuring natural ice, and there has, therefore, been considerable competition between the two products. For this reason it is important to notice in this connection the development of the natural-ice industry. Notwithstanding the fact that the custom of icing wines and drinks prevailed among the wealthier Greeks and Romans in ancient times and among Italians and Frenchmen in the Seventeenth century, natural ice as an article of commerce did not obtain importance until the beginning of the Nineteenth century. From the inception of the industry the United States has been the great field for

<sup>1</sup> Ice and Refrigeration, July, 1901, page 3.

both the production and consumption of ice, and the commodity which in the Eighteenth century was rated a luxury has now become almost a necessity. The year 1805 may be looked upon as marking the beginning of the industry in the United States. The pioneer was Frederic Tudor, of Boston, Mass., who in 1805 shipped a cargo of 130 tons of ice to the West Indies. Although the venture resulted in a net loss of about \$4,500, the cargo arrived at its destination in excellent condition. Two years later Mr. Tudor shipped a cargo of 240 tons to Havana, but this venture was likewise unprofitable. About the year 1812 he was granted by Great Britain a monopoly of the ice trade with her colonies in the West Indies, and later, 1815-16, he received the same concessions from Spain. From 1817 to 1820 he extended the trade to Charleston, S. C., Savannah, Ga., and New Orleans, La. In this way a large and profitable trade was established with the southern countries and with the southern ports of the United States. The ultimate success of Mr. Tudor prompted competitors to enter the field as exporters. The growth in the exports of ice between 1850 and 1900, shown in the following table, is taken from the reports of the bureau of statistics, Treasury Department:

EXPORTATION OF ICE.

YEAR.	Tons.	Value.
1850.....		\$107,013
1855.....	41,117	190,798
1860.....	49,153	183,184
1865.....	59,927	225,825
1870.....	65,802	267,702
1875.....	53,724	208,249
1880.....	45,666	136,686
1885.....	38,901	89,420
1890.....	44,849	111,762
1895.....	17,295	41,915
1900.....	13,720	29,501

It appears that the export trade in ice increased steadily until about 1870. After this date the exports of ice steadily decreased until in the year 1900 the number of tons exported was so insignificant that the foreign trade in ice may now be considered as practically extinct.

The growth of the domestic trade was simultaneous with the early increase in the export trade. In New York city ice was used by dealers in perishable goods as early as 1825, and the demand for it gradually developed in all the larger Eastern cities. The Civil War gave a decided impetus to the industry, as large quantities of ice were required for medical purposes in the hospital service. The rapidly increasing demand for ice in recent years is due in large part to the establishment and growth of industries which are dependent upon the use of this product. It has been impossible to obtain data relative to the production of the entire country, but some indication of the growth and extent of the industry may be obtained from the following table, which gives the quantity of ice harvested in the

state of Maine and on the Hudson River since 1878. Although these are the great harvesting regions of the country, their annual yield probably does not represent much more than half the ice harvest of the United States.

HARVEST OF MAINE AND HUDSON RIVER ICE SINCE 1878.<sup>1</sup>

YEAR.	Maine.	Hudson River.	Capacity of Hudson River ice houses.
	Tons.	Tons.	Tons.
1878.....		2,225,000	2,300,000

<sup>1</sup> Ice Trade Journal.

Some time before the natural-ice industry became a factor of commercial importance attempts had been made to produce ice by abstracting the latent heat from water by artificial means. The first machine for the manufacture of ice was invented in 1755 by Dr. William Cullen, and was based on the principle that the creation of a vacuum increases the evaporation of water and by this means produces ice. Cullen reduced the atmospheric pressure by means of an air pump. About 1810 the chemical affinity of sulphuric acid for water was discovered and ice was produced by its use. The invention of the first machine capable of producing ice in quantities sufficient for commercial use is generally accredited to Mr. Jacob Perkins, an American engineer residing in London. He obtained a patent for his machine in 1834. The refrigerant was ether, and the evaporator containing the same was inclosed in pipes through which brine circulated at a temperature of 5° F. Boxes filled with water were placed in a receptacle into which flowed the brine, freezing the water. The brine was then pumped back, and, after being exposed to the ether, could again be used. This machine is generally considered the forerunner of the modern compressor machine.<sup>1</sup> The use of the boxes developed into the use of cans and the manufacture of can ice. In order to describe adequately the development of the modern compressor and absorption machines it is necessary to mention several of the men prominently identified with the invention or improvement of ice-making apparatus.

<sup>1</sup> Ice and Refrigeration, August, 1901, page 46.

Prof. A. C. Twining, of New Haven, Conn., took out a patent for an ice machine in England in 1850 and in the United States in 1853. In 1855 he operated a machine in Cleveland, Ohio, which produced over 1,600 pounds of ice in twenty-four hours, and was operated intermittently until 1857. Although the Perkins machine was the forerunner of the compressor machine of the present time, the Twining machine more nearly represents the complete compressor system of to-day, and for this reason Professor Twining deserves the credit both for the invention of this system and for putting it into practical operation.<sup>1</sup> Professor Twining also discovered that ice frozen at a temperature slightly below the freezing point would be transparent with the exception of the small porous core, while if frozen at a lower temperature it would be opaque and porous throughout. A patent for the manufacture of ice by mechanical means was issued in 1857 to Dr. John Gorrie, of Appalachicola, Fla. The apparatus used by Dr. Gorrie is important in that it was the forerunner of the compressed-air machine later invented by Dr. Alexander

Kirk. In 1858-1860 Ferdinand P. E. Carre, a Frenchman, introduced an ice-making and refrigerating apparatus from which has developed the modern ammonia absorption system. It was by means of this machine that the trade in frozen meat was introduced to the world. The Carre machine was also the first to obtain prominence in the ice-making industry of the United States. In the infancy of the industry the ice was opaque, and it was not until about 1868 that transparent ice was made by the use of distilled water. Capt. David Smith, of Chatham, Mass., was the originator of the plate-ice system. He erected in Oakland, Cal., the first machine of this character.

From the inception of the United States Patent Office to January 1, 1902, there have been 4,337 patents granted for various processes of refrigeration. Of this number, 681 have been issued for the manufacture of ice machines. These various inventions prepared the way for the development of the manufactured-ice industry, which has already been described in the pages of the bulletin.

Table 11, which follows, shows in detail the statistics relating to the manufacture of ice, as reported by the 787 establishments engaged in this industry for 1900.

<sup>1</sup> Mechanical Refrigeration, De La Vergne Refrigerating Machine Company, 1887, page 9.

TABLE 11.—ICE MANUFACTURE, BY

	United States.	Alabama.	Arizona.	Arkansas.	California.
1 Number of establishments.....	737	23	9	18	20
2 Character of organization:					
3 Individual.....	179	4	1	4	2
4 Firm and limited partnership.....	183	5	4	3	2
4 Incorporated company.....	475	14	4	11	16
5 Capital:					
5 Total.....	\$38,204,054	\$681,667	\$228,670	\$637,639	\$1,805,971
6 Land.....	\$4,679,379	\$62,800	\$16,050	\$59,350	\$236,100
7 Buildings.....	\$7,327,014	\$79,900	\$49,916	\$80,365	\$166,553
8 Machinery, tools, and implements.....	\$22,852,158	\$489,600	\$136,000	\$415,006	\$806,135
9 Cash and sundries.....	\$3,285,503	\$49,367	\$26,704	\$82,918	\$97,183
10 Proprietors and firm members.....	459	13	11	11	7
11 Salaried officials, clerks, etc.:					
12 Total number.....	1,545	48	12	26	64
12 Total salaries.....	\$1,234,803	\$35,680	\$10,370	\$24,330	\$62,661
13 Officers of corporations—					
13 Number.....	446	16	2	11	12
14 Salaries.....	\$465,104	\$13,280	\$3,710	\$11,400	\$17,566
15 General superintendents, managers, clerks, etc—					
15 Total number.....	1,099	27	10	15	52
16 Total salaries.....	\$769,699	\$17,400	\$6,660	\$12,930	\$45,095
17 Men—					
17 Number.....	1,024	26	10	15	50
18 Salaries.....	\$740,232	\$17,300	\$6,660	\$12,930	\$44,095
19 Women—					
19 Number.....	75	1			2
20 Salaries.....	\$29,407	\$100			\$1,000
21 Wage-earners, including pieceworkers, and total wages:					
21 Greatest number employed at any one time during the year.....	10,814	249	66	244	265
22 Least number employed at any one time during the year.....	4,893	155	25	105	131
23 Average number.....	6,933	168	44	163	190
24 Wages.....	\$3,424,305	\$56,251	\$30,608	\$61,064	\$132,023
25 Men, 16 years and over—					
25 Average number.....	6,889	168	44	162	188
26 Wages.....	\$3,416,844	\$56,251	\$30,608	\$60,944	\$131,543
27 Women, 16 years and over—					
27 Average number.....	8				2
28 Wages.....	\$3,592				\$480
29 Children, under 16 years—					
29 Average number.....	36			1	
30 Wages.....	\$3,869			\$120	
31 Average number of wage-earners, including pieceworkers, employed during each month: <sup>2</sup>					
31 Men, 16 years and over—					
31 January.....	3,885	112	19	87	181
32 February.....	4,058	118	21	96	164
33 March.....	4,676	120	25	125	162
34 April.....	6,477	170	41	153	192
35 May.....	8,570	225	62	196	208
36 June.....	9,483	218	63	226	187
37 July.....	9,808	220	64	226	220
38 August.....	9,794	222	66	229	219
39 September.....	9,236	213	63	212	193
40 October.....	7,300	163	53	165	191
41 November.....	5,124	122	31	122	167
42 December.....	4,263	107	22	101	175
43 Miscellaneous expenses:					
43 Total.....	\$1,779,890	\$31,777	\$10,408	\$30,762	\$89,759
44 Rent of works.....	\$116,026	\$3,799	\$244	\$696	\$6,160
45 Taxes, not including internal revenue.....	\$246,340	\$4,289	\$2,470	\$4,288	\$6,256
46 Rent of offices, interest, insurance, and all sundry expenses not hitherto included.....	\$1,394,180	\$23,689	\$6,599	\$25,478	\$77,343
47 Contract work.....	\$23,344		\$1,095	\$300	
48 Materials used:					
48 Aggregate cost.....	\$3,339,724	\$63,399	\$41,505	\$51,700	\$119,839
49 Ammonia—					
49 Total cost.....	\$359,549	\$12,766	\$4,133	\$5,910	\$12,913
50 Total pounds.....	2,379,989	122,415	10,279	20,984	67,653
51 Ammonia, anhydrous—					
51 Cost.....	\$279,680	\$6,746	\$4,133	\$5,910	\$10,413
52 Pounds.....	1,056,535	24,989	10,279	20,984	32,653
53 Ammonia, aqua—					
53 Cost.....	\$79,869	\$6,021			\$2,500
54 Pounds.....	1,323,454	97,426			35,000
55 Fuel.....	\$2,144,316	\$28,185	\$32,851	\$32,118	\$68,558
56 Rent of power and heat.....	\$20,336		\$350	\$2	\$10,390
57 Mill supplies.....	\$216,383	\$4,396	\$1,391	\$3,824	\$4,897
58 All other materials.....	\$501,485	\$4,293	\$2,295	\$7,296	\$20,611
59 Freight.....	\$97,655	\$3,759	\$485	\$2,550	\$2,520
60 Products:					
60 Aggregate value.....	\$18,874,513	\$253,475	\$132,611	\$236,289	\$511,197
61 Ice—					
61 Total value.....	\$13,308,874	\$252,675	\$120,765	\$225,029	\$415,348
62 Total tons.....	4,294,439	55,908	14,709	51,236	90,679
63 Can ice—					
63 Value.....	\$12,863,160	\$252,675	\$120,765	\$225,029	\$353,888
64 Tons.....	4,139,764	55,908	14,709	51,236	80,679
65 Plate ice—					
65 Value.....	\$140,714				\$61,500
66 Tons.....	154,675				10,000
67 All other products.....	\$570,639	\$800	\$11,846	\$11,260	\$95,809
68 Comparison of products:					
68 Number of establishments reporting for both years.....	551	14	4	10	15
69 Value for census year.....	\$10,379,966	\$201,761	\$68,900	\$168,737	\$469,497
70 Value for preceding business year.....	\$9,841,233	\$179,406	\$56,500	\$159,071	\$435,706

<sup>1</sup>Includes the statistics for 12 establishments, the schedules for which were received too late to be included in the tables presented in Parts I and II, Manufactures. These establishments are distributed as follows: Alabama, 2; Arkansas, 3; Florida, 2; Louisiana, 2; Mississippi, 2; Oklahoma, 1.

MANUFACTURED ICE

The average number of women, 16 years and over, and children, under 16 years, employed during each month are not included in the table, because of the small number reported.

TABLE 11.—ICE MANUFACTURE, BY

	Maryland.	Mississippi.	Missouri.	New Jersey.	New Mexico.
1 Number of establishments.....	18	23	31	26	4
2 Character of organization:					
3 Individual.....	4	9	4	6	3
4 Firm and limited partnership.....	1	5	3	3	
5 Incorporated company.....	13	9	24	17	1
6 Capital:					
7 Total.....	\$649,692	\$597,871	\$1,835,166	\$1,653,028	\$118,450
8 Land.....	\$93,191	\$93,510	\$271,383	\$175,700	\$10,650
9 Buildings.....	\$100,100	\$94,061	\$406,038	\$306,470	\$29,000
10 Machinery, tools, and implements.....	\$421,425	\$372,210	\$977,152	\$970,344	\$72,000
11 Cash and sundries.....	\$34,976	\$38,090	\$180,593	\$110,514	\$6,800
12 Proprietors and firm members.....	6	14	13	12	3
13 Salaried officials, clerks, etc.:					
14 Total number.....	19	28	65	52	2
15 Total salaries.....	\$14,535	\$23,900	\$66,315	\$37,999	\$2,400
16 Officers of corporations—					
17 Number.....	6	8	26	16	2
18 Salaries.....	\$2,550	\$5,500	\$33,618	\$14,410	\$2,400
19 General superintendents, managers, clerks, etc.—					
20 Total number.....	13	20	39	36	
21 Total salaries.....	\$11,985	\$18,400	\$32,697	\$23,589	
22 Men—					
23 Number.....	13	20	35	35	
24 Salaries.....	\$11,985	\$18,400	\$30,593	\$23,439	
25 Women—					
26 Number.....			4	1	
27 Salaries.....			\$2,104	\$150	
28 Wage-earners, including pieceworkers, and total wages:					
29 Greatest number employed at any one time during the year.....	204	271	476	272	39
30 Least number employed at any one time during the year.....	113	111	169	148	15
31 Average number.....	138	162	279	183	22
32 Wages.....	\$74,633	\$56,503	\$157,006	\$94,070	\$15,300
33 Men, 16 years and over—					
34 Average number.....	137	160	279	182	21
35 Wages.....	\$74,318	\$55,519	\$157,006	\$93,570	\$15,200
36 Women, 16 years and over—					
37 Average number.....			1	1	
38 Wages.....			\$960	\$500	
39 Children, under 16 years—					
40 Average number.....	1	1			1
41 Wages.....	\$320	\$24			\$100
42 Average number of wage-earners, including pieceworkers, employed during each month: <sup>1</sup>					
43 Men, 16 years and over—					
44 January.....	96	60	134	102	12
45 February.....	76	67	149	128	12
46 March.....	105	79	178	153	12
47 April.....	127	133	250	179	15
48 May.....	151	227	335	220	24
49 June.....	180	272	381	233	30
50 July.....	187	275	412	234	31
51 August.....	188	258	429	241	36
52 September.....	186	236	379	237	27
53 October.....	143	171	327	206	19
54 November.....	104	76	215	136	16
55 December.....	96	62	137	117	16
56 Miscellaneous expenses:					
57 Total.....	\$24,490	\$33,730	\$72,868	\$51,276	\$1,933
58 Rent of works.....	\$185	\$120	\$6,720	\$4,325	
59 Taxes, not including internal revenue.....	\$5,972	\$6,995	\$10,224	\$7,510	\$1,033
60 Rent of offices, interest, insurance, and all sundry expenses not hitherto included.....	\$18,333	\$26,615	\$55,924	\$39,441	\$950
